# SIR,

T is the privilege of real greatnefs not to be afraid of diminution by condefcending to the notice of little things; and I therefore can boldly folicite the patronage of Your MAJESTY to the humble labours by which I have endeavoured to improve the inftruments of fcience, and make the globes

#### DEDICATION.

globes on which the earth and fky are delineated less defective in their construction, and less difficult in their use.

Geography is in a peculiar manner the science of Princes. When a private student revolves the terraqueous globe, he beholds a fucceffion of countries in which he has no more interest than in the imaginary regions of Jupiter and Saturn. But Your MAJESTY must contemplate the scientifick picture with other fentiments, and confider, as oceans and continents are rolling before You, how large a part of mankind is now waiting on Your determinations, and may receive benefits

#### DEDICATION.

nefits or fuffer evils, as Your influence is extended or withdrawn.

prey, and live at the mercy of wheels

The provinces which Your MA-. JESTY's arms have added to Your dominions, make no inconfiderable part of the orb alloted to human beings. Your power is acknowledged by nations whole names we know not yet how to write, and whole boundaries we cannot yet describe. But Your MAJESTY's lenity and beneficence give us reason to expect the time when fcience shall be advanced by the diffusion of happiness; when the defarts of America shall become pervious and fafe, when those who are now reftrained by fear shall be attracted CEORGE ADAMS.

#### DEDICATION.

attracted by reverence, and multitudes who now range the woods for prey, and live at the mercy of winds and feafons, shall by the paternal care of Your MAJESTY enjoy the plenty of cultivated lands, the pleafures of fociety, the fecurity of law, and the light of Revelation.

I am,

Trall Dec

### SIR, and and should shore

#### ADVERTISEMENT.

**BEING** encouraged to offer to the public a fecond edition of my TREATISE ON THE GLOBES, I thought myfelf engaged to confider, whether I might not be able, by a few additions, to render it more ufeful than the former.

And as fome observations on the folar system feemed to be wanting, I have berein endeavoured to supply that defect, by prefixing a short view of it.

I have also added fome pertinent problems, and extended the use of the Globes to the solution of all cases in Spherical Trigonometry, which are applied to a variety of astronomical problems; and that these additions might be more instructive and amusing, I have illustrated them by eleven copper plates.

## PREFACE.

THE connection of aftronomy with geography is fo evident, and both in conjunction are fo neceffary to a learned education, that no man will be thought to have deferved ill of the republic of letters, who has applied his endeavours to throw any new light upon fuch ufeful fciences. And as the phœnomena of the earth and heavens can be adequately illuftrated only by the mechanical contrivance of globes, whatever improvement is made in thefe must deferve regard, in proportion as it facilitates the attainment of astronomical and geographical knowledge.

As to maps and all projections of the fphere *in plano*, their use is more difficult than those of the globe, of which indeed they are only so many pictures; nor can they be thoroughly understood without more skill fkill in geometry than is commonly poffeffed by beginners, for whofe use the following treatife is principally defigned; tho' it also contains some observations, which I hope will not be altogether unacceptable to a more learned reader.

The globes now offered to the public, are of a conftruction new and peculiar; they are contrived to folve the various phœnomena of the earth and heavens, in a more eafy and natural manner than any hitherto publifhed, and are fo fufpended that the fludent may elevate the fouth pole; a thing impracticable in the ufe of the common globes.

That agreement too, which is here pointed out between the celeftial and terreftrial fphere, will be found to open a large field of geographical and aftronomical knowledge; and will afford both inftruction and amutement to every unprejudiced enquirer. This correspondence arises from a comparison of one globe with the other, or of the distances of different places on the earth's furface, with the relative distances of fuch fixed ftars as answer to them in the heavens.

xii

By

By these steps of science, the mind of man may be raifed to the contemplation of the divine wisdom, which has so adjusted the proportion of days, months, seafons, and years, in the different parts of the terraqueous globe, as to have distributed with an impartial hand, though after a manner wonderfully various, an equal scale of the science of t

By these globes, with little or no experience in astronomy, may be seen how the moon changes her place every night, by observing her position with respect to any fixed star, and how she proceeds regularly from it to the eastward; as the several planets also may be observed to do, some more flowly than others, as their orbits are more or less remote from the center of the system; while the regularity of their motions, strictly conformable at all times to the laws of their Creator, exhibits a striking pattern of obedience to every rational spectator.

But it will be proper in this place to inform the reader what he is to expect in the globes, and in the following treatife intended to accompany and explain them.

The

The fuperior accuracy with which the plates are drawn and engraved, will, it is hoped, appear to competent judges at the first fight; for the perfecting of which no expence of time or labour hath been spared. The celestial globe is improved by the addition of several thousand stars more than have appeared upon any globe hitherto publissed; all the latest discoveries in geography and astronomy are in both of them strictly followed, and many new lines and circles are inferibed, the use of which will be fully explained hereaster.

In the treatife, we have made choice of that method of finding the times of equinox, which is the most modern and fimple; and which perhaps gives the truest mean length of a tropical year; that the young student may with greater ease and pleasure be made acquainted with the first principles, and from them be carried on to the more abstruss parts of astronomy.

To render this book as extensively useful as possible, I have endeavoured, with all the clearness I am master of, to express both my own and the fentiments of other authors on the same subject; and I think it it my duty to acknowledge the affiftance I have received in the courfe of this work, as well from books, as from fome worthy friends; as I would not willingly incur the imputation either of plagiarifm or ingratitude. If there fhould appear to be any defects, to which every human work is liable, the reader, I hope, will make fome, favourable allowance for the undertaker of a tafk fo complicated and laborious, and correct my errors for himfelf, as well as he is able.

N. B. When the reader is hereafter directed to apply a card, or the edge of a card, to any part of the globe, it is to be understood that he should cut a card of any kind, exactly in the fize and shape of ABCD, fig. 4. for the globes of eighteen inches diameter; and of the fize and shape of E F G H, for those of twelve inches diameter; then, if the arch B C, or F G, are applied to the furface of their respective globes, the lines A B, or C D, EF, and GH, will become radii from the center of the globe. It is frequently required to know what point upon the strong brafs meridian, or broad paper circle, exactly anfwers to a given point upon the globe, and as this

this cannot be well known by infpection, on account of the necessary diftance of these two circles from the furface, if the corner B or F be applied to the given point upon the globe, the edge of the card will exactly mark the degree or part of the degree required.

For elevating the pole exactly, the card is to be laid upon the broad paper circle, and its edge applied to the ftrong brafs meridian, by which means the degree, and parts of a degree, may be alcertained with fufficient accuracy.

A

# COMPREHENSIVE VIEW

OF THE

# SOLAR SYSTEM.

STRONOMY, which is defervedly efteemed the most noble and exalted branch of human literature, regards the various phœnomena of

those heavenly bodies, which the invention of curious inftruments hath brought within our observation, from the surface of the terrestrial globe.

It difcovers to us their fituation, magnitudes, diftances, and motions; and enables us to determine with precision the length of years, months, and days, and to account for the vicifiitudes of the scafons; and, in a word, explains whatever falls within our

con-

confideration, as the proper subject of this useful and interesting study.

#### The Solar System

1. Confifts of the fun, (from which it receives its denomination,) fix primary, ten fecondary planets, and the comets. Thefe, with that collection of innumerable fpherical bodies which compose the universe, are called the system of the world; all which appear to the inhabitants of the earth, as if they were within one and the fame concave sphere.

2. The Copernican, or folar, fystem supposes the fun in the center, having a motion round its axis, which is completed in about  $25\frac{1}{4}$  days. This motion was discovered by the revolution of those spots, which are frequently seen in its disc, and are supposed to adhere to its surface; and its axis is inclined to the plane of the ecliptic in an angle of about  $87\frac{1}{4}$  degrees.

3. The fix primary planets move round the fun in their respective elliptical orbits, from west to east, at different distances, and

in

in various periodical times. Their names and characters, in the order in which they revolve about the fun, are expressed in fig. 2, and are as follows:

Mercury, Venus, The Earth, Mars, Jupiter, Saturn. Q Q J h

4. The planets are diffinguished from the fixed stars, by their motion, and the steadiness of their light. The apparent diameter of the fixed stars is fo small, by reafon of their immense distance, that every small atom floating in our atmosphere intercepts their light, and causes them to twinkle. But that of the planets being greater, as they are nearer to us, they shine with a steady light.

5. The fixed stars keep their places and distances with respect to each other, but the planets change theirs, from one part of the heavens to another.

6. Some of the primary planets are attended with fmaller, called fecondary planets, moons, or fatellites. Our earth is attended by the moon; Jupiter by four, and Saturn by five fatellites; the nine last are not visible without the affistance of a telescope.

7. The

4

ting 5

7. The observation of comets, seen sometimes within the limits of the solar system, hath been hitherto so imperfect, that we shall only take notice for the present, that they are supposed to move round the sun, in very eccentric orbits, and appear to us only when they are in that part of their orbit nearess the sun in they move in various directions and inclinations; the lower part of one of these orbits is represented in fig. 2.

As the fun has a number of planets and comets moving round him, fo every fixed ftar is fuppofed to be a fun, and to have a fystem of its own.

#### The orbits of the planets.

8. The path defcribed by a planet in its motion round the fun is called its orbit. In fig. 2. their feveral orbits are reprefented, by concentric circles: the paths which they defcribe are elliptical, and the fun is in one of the foci. In fig. 3. A T P V is an ellipfe, A P its transverse, V T its conjugate diameter, S and N are its two foci, C is the centre of the ellipse; the distance between C S or C N is called the eccentricity.

9. The

9. The orbit of every planet is in a plane paffing through the fun, which planes are inclined to one another : thus in fig. 4. let ABCD represent the earth's orbit, or plane of the ecliptic; this is taken for a ftandard, from which the inclination of each orbit of the planets, as EDFB, is measured. The inclination of the orbit of Mercury is  $6^{\circ}$ , 52', that of Venus 3., 33', of Mars  $1^{\circ}$ , 52', of Jupiter  $1^{\circ}$ , 20', and of Saturn  $2^{\circ}$ , 30'.

10. To a spectator from the sun, the planes of the orbit of each planet produced to the fixed stars would mark, in the celess orbits; their several inclined heliocentric orbits; their passage through these is their heliocentric motion. These extended planes, to a spectator on the earth, mark out in the starry sphere their geocentric orbits; and their apparent motion through these, is called their geocentric motion.

11. The latitude of a planet feen from the earth, is called its geocentric, if feen from the fun, its heliocentric, latitude.

## The nodes of a planet's orbit

12. Are two points in which it interfects the plane of the ecliptic. In fig. 4. ABCD 6

ABCD is the plane of the ecliptic; EBFD is the orbit of a planet, in which the points B and D are the two nodes. B the alcending, D the defcending node; the point E is called its greatest northern, and F its greatest fouthern limit.

13. The line of the nodes is a line BD drawn through the fun from one node to the other.

A planet, feen from the earth, never appears in the ecliptic, but when it is in one of its nodes : in all other parts of its orbit it has geocentric latitude.

# The inferior planets

14. Are Mercury, and Venus; they are called inferior, because their orbits are included within that of the earth; see fig. 2.

#### Mercury

15. Moves round the fun in 87 d. 23 h. 16 m. which is called his periodical time. If we call the mean diftance of the earth from the fun 1000, the mean diftance of Mercury is 387, his eccentricity 80. No fpots have yet been observed in Mercury; there-

therefore it is not certainly known whether he turns about his axis or not; but it is most probable that he does.

Venus

16. Performs her revolution round the fun in 224 d. 16 h. 49 m. which is called her periodical time; her mean distance is 724, and her eccentricity 5; her motion about her axis is performed in 24 days, 8 hours, according to Bianchini; and the inclination of her axis to the plane of the ecliptic, is 15 degrees.

17. The greatest distance of the earth, or of any planet from the fun, is called its aphelion, or higher apfis; its leaft distance is called the perihelion, or lower apfis. Thus in fig. 3. A is the place of the aphelion, P that of the perihelion. The axis P A of any planet's ellipfis, is called the line of the apfides; the extreme points of its flortest diameter TV, are the places of its mean distance from the fun; and ST, or SV, the line of its mean distance.

18. A planet is faid to be in conjunction with the fun, when its apparent place, feen from the earth, is in or near the fun's place;

B 4

place; it is faid to be in opposition, when the earth is between the fun and planet.

# The elongation of a planet

19. Is its apparent diftance from the fun, as feen from the earth. A planet has no elongation when in conjunction with the fun; in oppofition, it has 180 degrees. In fig. 5. t T t reprefents a part of the earth's orbit; T the earth, S the fun; A C E an arch of the ftarry fphere, and d the place of Venus in her orbit. A fpectator upon the earth at T would refer the fun's place to those fixed ftars at C, and that of Venus to those at D: in this case the angle C T D is the apparent diftance between the fun and Venus, and is called the angle of elongation.

20. An inferior planet may be in conjunction with the fun in two fituations; 1. when it is between the earth and the fun, called the inferior conjunction; 2. when the fun is between the earth and planet, called its fuperior conjunction; but it can never be in opposition to the fun.

21. The greatest elongation of an inferior planet is when a line T E, drawn from the earth

earth at T, through the planet at c, is a tangent to the orbit of the planet.

22. As an inferior planet moves from its greatest elongation at a, fig. 5. through c, its superior conjunction, to c, its greatest elongation on the other side of the sun, its geocentric motion is direct.

23. When the earth is at T, Venus at a, a spectator at T sees the planet at a, in the line TaA among the fixed stars at A: when the planet is come to b, it appears in the line T b B, or amongst the stars at B; at c, it is in its fuperior conjunction, and feen among the stars at C; at d, it appears among the ftars at D; and when it arrives at e, it appears among those at E. In this motion, Venus appears to defcribe the arc ABCDE. in the concave fphere of the heavens: and as these letters are in the same direction with abcde, which express the planets motion round the fun, its apparent motion feen from the earth is therefore direct, from weft to eaft, or according to the order of the figns.

24. An inferior planet passing from e, its greatest elongation, through f, its inferior conjunction, to a, its greatest elongation on the

10

1000

the other fide of the fun, its geocentric motion is retrograde.

As Venus is moving from e to n, the appears in the line T n d D, and is feen among the ftars at D; when the comes to f, her inferior conjunction, the appears amongft the ftars at C; at m, the is feen in the concave fphere at B; and when the is at a, in her own orbit, the appears at A, in the heavens. Hence, as the planet patted through e n f m a, in its natural motion, its apparent motion was backwards, through E D C B A, or contrary to the order of the figns.

25. When the inferior planets are at their greatest elongation, they appear stationary, or continue in the same place for some time, before their motion changes from direct to retrograde, or from retrograde to direct again.

The time of the retrogreffion of Venus is about 40 days, of Mercury, 18 days.

26. In order to have a clear idea of the apparent motion of a planet, conceive the lines T a A, T b B, &cc. to move with the carth; fo that the points e n f m a, whilft the earth performs its revolution, may run through the orbit of the planet.

27. The

27. The inclination of the orbits of the plalanets to the plane of the ecliptic, is the cacaufe, why they do not feem to move in the eccliptic line, but are sometimes above, and atat others below it. In fig. 6. let NVNQ ble a circle in the plane of T t the ecliptic, arand NAN, the planet's inclined orbit, S the fun, the earth at T, and the planet at AA; if the thort line VA be imagined perppendicular to the plane of the ecliptic, and teto pass through the planet at A, the angle VVTA, is the latitude of the planet, which it is called the geocentric latitude, to diftin-E guish it from the heliocentric latitude, as I feen from the fun, which is reprefented by t the angle ASV.

28. When a planet is in the node at N, i it appears in the ecliptic line; as it recedes from thence its latitude increases; and this is different, according to the situation of the earth; so that the latitude is greater when the earth is at T, and the planet at A, than when the earth is at t, and the planet at V.

29. A planet is faid to be in quadrature when it is 90 degrees diftant from the fun; the inferior planets cannot be in quadrature, as their greatest elongation can never

be

FI-

be a tight angle; therefore they never appear far from the fun; for Venus and Mercury are only feen in an evening towards the weft, foon after fun-fet, or a little before the fun rifes in the morning. The greateft elongation of Mercury is 33 degrees, and of Venus 48 degrees.

30. As Venus moves from her fuperior to her inferior conjunction, fhe fets after the fun, and is called the evening-ftar; and as fhe is moving from her inferior to her fuperior conjunction, fhe rifes before the fun, and is called the morning-ftar.

31. The fun, being larger than any planet, enlightens a little more than an hemisphere; and as we can only see half a planet at once, that hemisphere which we see is called the disc of the planet. The inferior planets are not visible to us, when in their inferior conjunction, but their whole disc is illuminated in their superior conjunction: and when they are in one of their nodes, they appear on the disc of the fun like a black spot; and this is called a transit of the planet across the disc of the fun. As the enlightened hemispheres of the inferior planets are sometimes more, at others less,

lefs, turned towards the earth, they appear through a telescope to have all the phases of the moon.

32. When Venus is the evening-ftar, her horns are turned towards the caft, and the fun fets before, and to the westward of her. When the is a morning-ftar, her horns are turned towards the west, and the sun rifes after, or to the east of her; in both cafes, the horns are always turned from the fun. When the is at her greatest elongation, half the enlightened hemisphere will face the earth, and her difc appear as the moon does in the quarters; but when in any part between that and her inferior conjunction, the appears horned, and between her greateft elongation and fuperior conjunction, her appearance is gibbous.

33. What has been faid of the planet Venus, is also true with respect to Mercury, with this difference, that he is direct, stationary, &c. fo much more frequently, as his revolutions round the fun are performed in a shorter space of time.

# The earth.

10 113

34. The apparent motion of the fun, otto arifing

the brbie afforts

ariting from the earth's annual motion in its orbit, is as follows: In fig. 7. S reprefents the fun, T, the earth in its orbit T t; and R Q the concave fphere of the fixed ftars. Whilft the earth is moving in its orbit from T to t, the fun feems to move thro' the ftarry arch from Q to R, which meafures the angle R S Q, equal to the angle T S t, fo that the celerity of the apparent motion of the fun depends upon the celerity of the angular motion of the earth, with refpect to the center of the fun. In a whole revolution of the earth, the fun alfo feems to run through a whole circle.

35. The earth moves round the fun between the orbits of Venus and Mars, in 365 days, 5 hours, 49 minutes. Befides this annual motion, it turns round its own axis in 24 folar hours; its axis is conftantly inclined in an angle of  $66\frac{1}{2}$  degrees to the plane of the earth's orbit, or the ecliptic, and keeps continually parallel to itfelf in every part of its revolution.

In fig. 8. S reprefents the fun, A BCD the orbit of the earth; in the periphery of which, the center of the earth is carried round the fun, according to the order of the

------

-----

the figns, or in confequentia.  $\Im S = rc$ presents the equinoctial colure,  $\Im S \vee s$ , the folfitial colure; the circle in each, a b c d, represents the earth in the four cardinal points of its orbit; in which d c separates the enlightened part c b d of the earth's disc, from d a c, the obscure part of it.

The plane of the earth's annual orbit, A B C D, extended every way to the fphere of the fixed flars, would defcribe the celeftial ecliptic, which would coincide with the terreftrial ecliptic, here reprefented by each of the circles a b c d; in which e, is the pole of the ecliptic, P the pole of the world, or of the equator: in all these projections, x is the equator, t the tropic of Cancer, L the path or vertex of London; and the circles cutting each other in P the pole of the world, are circles of right ascenfion in the celeftial, and of longitude in the terreftrial fphere.

36. As the fun always enlightens one half of the earth's globe at the fame time, the line d c, that divides the illuminated from the obfcure part of the earth's difc, is called the edge of the difc.

and the man the day will then

P a, P d, P b, P c, reprefent fo much of the earth's axis as falls within these projections; these may be called the line of direction of the earth's axis, which is constantly carried round the annual orbit, always parallel to itself.

37. The inclination of the earth's axis will be better underftood by obferving fig. 9. in which ABCD represents the earth's orbit, feen at a diftance; the eye fupposed to be elevated a little above the plane of it. The earth is here reprefented in the first point of each of the twelve figns, as marked in the figure, with the twelve months annexed : e the pole, and ed the axis of the ecliptic, always perpendicular to the plane of the orbit. P the north pole of the world, Pm its axis, about which the earth's daily motion is made from weft to east. PCE shews the angle of its inclination, which preferves its parallelism through every part of its orbit.

38. When the earth is in the first point of Libra, the fun then appears in the opposite point of the ecliptic at Aries, about the 22d of September, N. S. and when the earth is in Aries, the fun will then appear

appear in Libra about the 19th of March; at which times of the year the edge of the enlightened hemisphere is parallel to the folfitial colure, fig. 8. and passes thro' the two poles of the world, dividing every parallel to the equator into two equal parts; whence the diurnal parallel of every inhabitant on the furface of the earth will, at either of these feasons, be half in the illuminated, and half in the obscure part of the earth; confequently the day and night will be equal in all places.

39. Conceive the earth to have moved from = Libra to vs Capricorn, its line of direction keeping its parallelism will now coincide with the folftitial colure, fig. 8. and the edge of the difc will be perpendicular thereto, and pass through e, the pole of the ecliptic. In this fituation of the earth, all places within the northern polar circle are illuminated throughout the whole diurnal revolution ; at which time their inhabitants fee the fun longer than 24 hours; but those which lie under the polar circle touch the edge of the difc, and therefore their inhabitants only fee the fun skim quite round their horizon at its first appearance; every other parallel

parallel interfects the edge of the difc; and as the illuminated part of each is much greater than the obfcure part, the days are confequently at this feafon, of the fummer folftice, which happens about the 21ft of June, longer than the nights. While the earth is moving from Libra, through Capricorn to Aries, the north pole P, being in the illuminated hemitphere, will have fix months continual day; but while the earth paffes from Aries through Cancer to Libra, the north pole will be in the obfcure part, and have continual night; the fouth pole of the globe at the fame time enjoying continual day.

40. When the earth is at Cancer, the fun appears at Capricorn. At this feafon the nights will as much exceed the days, as the days exceeded the nights, when the earth was in the oppofite point of her orbit; for the nocturnal arches, or obfcure part of their paths, are here equal to the illuminated parts, when the earth was at Capricorn; and the illuminated part is here no more than the obfcure part was in that place.

I TOMA IL POPTA TITLE AN TA POSTION

Our

# Our fummer is nearly eight days longer than the winter.

41. By fummer, is meant the time in which the earth is moving in her orbit from the vernal to the autumnal equinox; and by winter, the time in which it is paffing from the autumnal to the vernal equinox. Upon the globe it is evident that the ecliptic is divided into fix northern and fix fouthern figns, and that it interfects the equator at the points marked Y and A. In our fummer, the fun's apparent motion is through the fix northern, and in winter through the fix fouthern figns; yet the fun is 186 d. 11 h. 51 m. in paffing thro' the fix first, and only 178 d. 17 h. 58 m. in passing through the fix last. Their difference 7 d. 17 h. 53 m. is the length of time by which our fummer exceeds the winter.

42. In fig. 16. A BCD represents the earth's orbit; S the fun in one of its foci: when the earth is at B, the fun appears at H in the first point of Aries; and whilst the earth moves from B, through C to D, the fun appears to run thro' the fix northern figns,  $\Upsilon \heartsuit \Pi \oslash A$  In to  $\Rightarrow$  at F. When the C 2 earth earth is at D, the fun appears at F in the first point of Libra; and as the earth moves from D thro' A to B, the fun appears to run thro' the fix fouthern figns,  $\simeq \pi \times \times$ to Aries at H. Hence the line F H, drawn from the first point of  $\gamma$ , through the sun at S, to the first point of  $\Rightarrow$ , divides the ecliptic into two equal parts; but the fame line divides the earth's elliptical orbit ABCD into two unequal parts, (the fun not being in the center, but in one of the foci of this orbit;) the greater part BCD, is that which the earth defcribes in fummer, whilft the fun appears in the northern figns; the lesser part is DAB, which the earth defcribes in winter, whilft the fun appears in the fouthern figns. C the earth's aphelion, where it moves the flowest, is in the greater part; A its perihelion, is in the leffer part, where the earth moves fastest.

43. The fun's apparent diameter is greater in our winter than in fummer, caufed by the earth being nearer to the fun, when in its perihelion at A in winter, than it is in the fummer, when in its aphelion at C; which is its greatest distance. The fun's apparent

apparent diameter in winter is 32 min. 47 fec. in fummer 31 min. 40 fec.

If the mean diffance of the earth from the fun be called 1000, its eccentricity will be 17; its greatest diffance 1017, and its least diffance 983.

## The fuperior planets.

44. The apparent motions of the fuperior planets agree in many refpects with those of the inferior ones, which have been already explained.

#### Mars, Jupiter, and Saturn,

Are called superior planets. See fig. 2.

45. If the mean diffance of the earth from the fun be called 1000, the mean diffance of Mars is 1523, its periodical time 686 d. 23 h. its eccentricity 141, and it turns round its axis in 24 h. 40 min. The planet Mars appears much larger and brighter when it is in opposition to the fun, than when it is in conjunction with him. Mars appears gibbous, when it is in quadrature, but full and round in conjunction or oppofition.

46. Ju-

46. Jupiter is the largeft of all the planets, fee fig. 13. he revolves in 9 h. 56 m. about his axis, which is nearly at right angles to the plane of his orbit, in which he moves about the fun in fomewhat lefs than 12 years, or 4332 days 12 hours. His mean diftance from the fun is 9538, and eccentricity 250. Several fpots have been feen on Jupiter's furface, which appears to be furrounded by feveral belts, or girdles, parallel to his equator: thefe vary in breadth and diftance from one another. See fig. 13.

47. Saturn is the farthest of all the planets from the fun; his mean distance is 5201, eccentricity 141; he is 29<sup>1</sup>/<sub>2</sub> years in moving through his orbit round the fun, or 10759 days 7 hours. It is not yet known whether Saturn turns round his axis or not; but he is attended with a broad thin ring, as reprefented in fig. 12. The edge of this ring reflects little or none of the fun's light to us: the planes of it reflect the light of the fun in the fame manner in which the planet does. The plane of the ring is inclined to the plane of the ecliptic at an angle of about 31 degrees. If we suppose the diameter of Saturn to be divided into four equal parts, the

the diameter of the ring will be about nine fuch parts. The diffance of the inner edge of this ring, from the body of the planet, is equal to the breadth of the ring. Through this fpace, between the planet and his ring, the fixed ftars may fometimes be feen.

48. The plane of Saturn's ring is parallel to itself in every part of its orbit. If the plane of the ring be produced to the fphere of the fixed stars, it will cut Saturn's heliocentric orbit in two opposite points, called the nodes of the ring. As Saturn passes from the ascending to the descending node of his ring, the northern fide of the plane of the ring is turned towards the fun; as it moves from the defcending to the afcending node of the ring, the fouthern fide of its plane is towards the fun. When Saturn's ring appears elliptical, as in fig. 12. the parts about its longest axis reaching beyond the planet's disc, are called anfæ, which a little before and after the difappearance of the ring, are unequal in magnitude. When Saturn is in the heliocentric place of either of the nodes of his ring, its plane produced passes thro' the fun, and then the ring becomes invisible to us.

C 4

The

The fuperior planets are fometimes in conjunction with the fun, fometimes in quadrature, and fometimes in opposition.

49. When the earth is in fuch a flation, that a line drawn from a fuperior planet to the earth becomes a tangent to the earth's orbit, the fuperior planet appears flationary. If the earth be at a or g, fig. 10. or 11. and the planet at I; I g, and I a, are tangents to the earth's orbit; in which places the planet feems to fland flill, or to have no geocentric motion.

50. When a fuperior planet, fig. 10. is moving from one of its apparent flations A, through its conjunction D to G, its geocentric motion is direct.

Fig. 10. Whilft the earth is moving from a, through d to g, a fuperior planet at I, appears to move in ADG, the concave fphere of the heavens, from A, through its conjunction D, to its other flation G; whence its apparent motion feen from the earth is direct, or *in confequentia*, which is from weft to eaft, according to the order of the figns.

51. Observe in fig. 10. that one end a of the line a IA, drawn from the earth at

а,

and a la c

a, through the planet's place at I, to the concave starry sphere ADG, attends the earth, as it moves through a b c d e fg; and the middle of it is supposed to turn round upon the planet as a center at I, the other end A will then mark out the planet's apparent motion in the heavens. So that the arch ABCDEFG, will be that which the planet appears to describe; and therefore the order of the letters expresses its motion in confequentia.

52. When a fuperior planet is passing from one station to the other thro' the oppofition, its geocentric motion is retrograde.

As the earth is paffing from g, fig. 11. through k to a, the planet at I appears to move from G, through K its opposition, to A; in this cafe, the apparent motion of the planet at I, feen from the earth, is retrograde, or *in antecedentia*, that is, from east to west, or contrary to the order of the figns. If the end g of the line gIG, fig. 11. attends the earth through gmlknha, and the middle of this line turns round upon the planet at I, the other end G will defcribe the arch GMLKNHA, which is contrary to the order of the letters in fig. 10. and therefore retrograde.

ra. The

53. The time of the retrogression of Mars s about 3 months; of Jupiter, 4 months; and of Saturn,  $4\frac{1}{3}$  months.

The planets viewed through a telescope are stripped of their adventitious rays, and appear like circular planes, of a determinate magnitude, whose diameters may be meafured by a micrometer.

54. The fuperior planets are fometimes nearer our earth than at other times; whence they appear larger or lefs, according to their different diffances from us. And as they are nearer to us than the fixed ftars, they may pafs between us and fome of the ftars: and as they go round the fun in orbits larger than that of the earth, they always turn much the greateft part of their illuminated hemisphere towards the earth, and therefore appear at all times round, or full, except only Mars, which in the quadratures is a little gibbous.

## The fecondary planets.

55. Three of the primary planets, viz. the Earth, Jupiter, and Saturn, in their revolutions round the fun, are attended with leffer planets, which move round each of their

Plate 5.

their respective primaries, according to the order of the figns.

# The Moon

56. Moves round the earth in an orbit, whole semidiameter is about 60<sup>+</sup> femidiameters of the earth; its eccentricity  $3\frac{1}{2}$  of the earth's femidiameters; the plane of the earth's orbit, produced to cut the plane of the ecliptic, makes an angle with it of about 5<sup>±</sup> degrees. The points wherein it interfects the ecliptic, are called the moon's nodes; these nodes have a flow regreffive motion of 19°, 19', 43", in a year, which carries them round the ecliptic, contrary to the order of the figns, in 18 years 234 days. The moon's periodical time is 27 d. 7 h. 43 m. and her rotation round her axis is performed in the fame time. Her eccentricity and inclination are both variable. The orbit which the moon defcribes round the earth is elliptical, the earth being in one of its foci; and when the moon is at her greatest diftance from the earth, or in her higher aplis, fhe is faid to be in apogeo; and when in her lower apfis, or least distance, in perigæo.

57. When

57. When the moon is at A, fig. 14. in conjunction with the fun at S, and the earth at T, it is called New Moon; and when in oppofition at E, it is called Full Moon. The fyzigies of the moon is a common term to express both its conjunction and opposition.

58. The moon's afcending node is called the Dragon's Head, and is thus marked  $\alpha$ ; its defcending node the Dragon's Tail  $\sigma$ .

59. A periodical month contains 27 d. 7 h. 43 m. in which time the moon defcribes her orbit; a fynodical month contains 29 d. 12 h. 43 m. 3 fec. which is the time that paffes between one new or full moon, and the next of the fame name which fucceeds it; this is longer than a periodical month about 2 days 5 hours.

60. In fig. 15. S reprefents the fun, A B part of the earth's orbit, ML reprefents a diameter of the moon's orbit, when the earth is at C; and m l another diameter, parallel to ML of the fame orbit, when the earth is removed to D. Whilft the earth is at C, and the moon at L, in conjunction with the fun, as the earth moves from C to D, and the moon's orbit moves with it, the

29

the diameter ML will then be in the pofition ml; fo that when the moon has defcribed its orbit it will be at l; but then the fun being at S, the moon will not yet be in conjunction; therefore the periodical month is completed before the fynodical, and before the moon can come into conjunction with the fun. When the earth is at D, fhe muft move from I to e, in the diameter g e; whence, befides going round her orbit, fhe muft defcribe the arc le, confequently the fynodical is longer than the periodical month by the quantity of the arc le.

61. We do not fee the moon at the conjunction, but at the opposition her whole difc is enlightened.

In fig. 14. a T b reprefents a part of the earth's orbit, S the fun, T the earth, ACEG the moon's orbit. If the moon is at A, it will be on the fame fide of the earth with the fun, or in conjunction; and the fun will then be beyond the moon: therefore the fun does not fhine on that hemisphere of the moon towards us; whence to us her whole disc must be dark.

daid w room all me do the 62. When

62. When the moon is at E, it will be in opposition, and the earth between it and the fun; confequently that hemisphere which is visible to us, will be the same hemisphere upon which the fun shines, therefore her whole disc towards us will be enlightened, or the moon will be full.

63. Fig. 14. The moon's difc is half enlightened when the is near the quadratures at C or G, her apparent distance from the fun at S being then 90 degrees: when the moon is between the conjunction at A, and either of the quadratures G or C, the illuminated part of it appears horned, as at H and B. When between the full at E, and the quadratures G or C, the difc appears gibbous, as at D and F. When the moon is at A, it is new; as fhe moves from A to C, it is faid to be in the first quarter ; from C to E, in the fecond quarter; from thence to G, in the third quarter; and from G to A again, in the last quarter.

After the new moon, her horns are turned towards the east, and before new moon towards the west; and when she is horned, that part of her disc upon which the

the fun does not shine, has yet light enough to make it faintly visible.

The fame fide of the moon is always turned towards the earth, and her furface is not fmooth, but uneven and mountainous, as may be feen with the affiftance of a telefcope, either in the first or last quarter.

The fatellites of Jupiter and Saturn.

64. The diftance of Jupiter's innermost fatellite from his center is 5.667 femidiameters of the planet; the fecond, 9.017; the third, 14.384; and the fourth, 25.299 femidiameters.

The periodical time of Jupiter's first fatellite is 1 d. 18 h. 27 m. 34 fec. The fecond is 3 d. 13 h. 13 m. 42 fec. The third is 7 d. 3 h. 42 m. 36 fec. And the fourth is 16 d. 16 h. 32 m. 9 fec.

65. The plane of the orbit of every fecondary planet is parallel to itfelf in every part of the orbit of its primary. The orbits of all Jupiter's fatellites are nearly, but not exactly, in the fame plane; which produced makes an angle with the orbit of Jupiter of about 3 degrees; the fecond deviates a little from the reft. 66. A

66. A fatellite in one of its nodes appears in the orbit of its primary: in all other parts of its orbit it has latitude.

If the plane of any circle produced paffes through the eye, it appears to be a ftraight line; confequently every circle, viewed obliquely, will appear elliptical; fo that

When a fatellite is in its node, at the fame time that its primary's heliocentric place is in the fame degree of the ecliptic with it, and the earth in its geocentric node; at that time the orbit of the fatellite appears a ftraight line. When the primary is in any other part of his orbit, the fatellite's orbit will appear an ellipfis, whofe fhorteft axis increafes in proportion as the primary is farther diftant from the fatellite's node.

The orbit of the earth is fo finall, when compared to those of Jupiter and Saturn, that in whatever part of her orbit she may happen to be, when either of these planets are in the nodes of their fatellites, these last will appear to describe lines very nearly straight.

67. When a fatellite is in that femicircle which is farthest from the earth, its geocentric motion is direct; when it is in that nearest

nearest to the earth, its geocentric motion is retrograde.

Any fatellite is at its greatest elongation from its primary, when a line, supposed to be drawn from the earth through the fatellite, is a tangent to the fatellite's orbit.

In fig. 17. BaC reprefents a part of Jupiter's orbit, NALM, the earth's orbit, S the fun, DGFH the orbit of Jupiter's outermost fatellite. When the earth is at A, and the fatellite at E or D, in the tangent line AE or AD, then this fatellite, feen from the earth at A, will appear at a greater distance from the primary, than it can do in any other fituation.

68. Every fatellite appears in conjunction with its primary, when it is between the carth and its primary; and alfo, when the primary is between the earth and fatellite; the first is called its inferior, the last its superior conjunction.

The apparent motion of any fatellite is direct, as it passes from D, fig. 17. its greatest elongation, through P, its superior conjunction, to E, its greatest elongation on the other fide; its geocentric motion seen from the earth at A, being then from west to D east,

34

east, in confequentia, or according to the order of the figns.

Any fatellite's apparent motion is retrograde, as it paffes from E, its greateft elongation on one fide of its primary, thro' H, the inferior conjunction, to D, its greateft elongation on the other fide ; it is therefore plain, that its motion feen from the earth at A, is from east to west, *in antecedentia*, or contrary to the order of the figns.

69. The fatellites are feen fometimes to the weft, and fometimes to the east of their respective primaries: they cannot be feen in their superior conjunction, and are feldom diffinguished from their primary in their inferior conjunction.

70. The diftance of Saturn's innermost fatellite from the center of the primary, is 1,93 femidiameters of the ring, the fecond 2,47, the third 3,47, the fourth 8,00, and the diftance of the fifth 23,45 femidiameters of the ring.

The periodical time of Saturn's innermost fatellite is 1 d. 21 h. 18 m. 27 fec. The second, 2 d. 17 h. 41 m. 22 sec. The third, 4 d. 12 h. 25 m. 12 sec. The sourth, 15 d. 22 h. 41 m. 14 sec. And the sistent fatellite's

fatellite's periodical time is 79 d. 7 h. 48 m.

71. The fatellites of Jupiter and Saturn caft a fhadow upon their primary, which may be feen to pafs over the difc of the planet like a fpot; they alfo frequently fall into the fhadow of their primaries, and are eclipfed; which may be observed by the help of a telescope.

72. Fig. 12, 13. represent the different magnitudes of the primary and secondary planets, with the proportion which they bear to each other, and to a globe of twelve inches diameter, which is supposed to represent the sun.

# The parallax of the heavenly bodies

73. Is the change of their apparent places, when viewed from different stations.

The diurnal parallax is the change of the apparent place of a fixed ftar or planet, or of any celeftial body, arifing from its being viewed on the furface, or from the center of the earth. The fixed ftars have no diurnal parallax, the moon a confiderable one : that of the planets is greater or lefs, according to their diftances.

D 2

74. In

74. In fig. 18. JAK represents the earth, T its center, AB the fenfible, T.L the real horizon of a spectator upon the earth at A, M the moon, S the fun, both in the fenfible horizon : if feen from A, they will appear in the horizon at B; but if feen from T, the center of the earth, they would appear amongst the fixed stars at C and D: that is, the moon would appear in the line TMD, and the fun in the line TSC: these are called their true places; the arch BC is called the fun's parallax, and BD that of the moon. The angles BSC, and BMD, are called the parallactic angles, which are respectively equal to the angles AST, and AMT; under which, AT, a femidiameter of the earth paffing thro' A. the place of the. spectator, 'would appear, if feen from the fun or moon.

75. If a planet is above the horizon at E, its true place feen from T, the center of the earth is at F, its apparent place at G, and its parallax is F G. Hence it is plain, that the higher the planet is elevated above the horizon, the lefs is its parallax; and when it is directly over the head of the fpectator at H, it will have no parallax at all;

all; its apparent place in the heavens being Z, whether it be feen from A or T. It is obfervable, that the apparent place G, of a planet at E, feen from the earth at A, is always lower or farther from the zenith Z, than F, its true place feen from T, except. when the planet is vertical, or at H; fo that the horizontal parallax is greateft of all.

76. The diurnal parallax of a planet in a vertical circle caufes one of right afcenfion and declination, unlefs it be on the meridian, when there is only a parallax of declination: it also caufes a parallax of longitude and latitude, unlefs the vertical circle is a fecondary of the ecliptic.

In fig. 18, W L represents the horizon, V T an arch of the equator, cutting the horizon at T; T P the axis of the world, and P the celestial pole, Z the zenith, Z X a vertical circle, R the planet's apparent place therein, if feen from the earth's furface; and Y its apparent place in the fame vertical, if it could be feen from the earth's center: then R Y is its parallax. P R O is a fecondary of the equator, passing through the planet, and P Y Q, another fecondary, passing through its apparent place at Y; D 3 whence

whence its declination, feen from the center, is OR, and from the furface QY; the difference NY, between QY and QN, is the parallax of declination. When the planet is at R, the fecondary PRO, paffes through the point O of its right afcenfion upon the equator, but the fecondary PYQ, paffes thro' Y, the planet's apparent place, and Q its right afcenfion upon the equator; whence the parallax RY, makes a difference, or parallax, QO, in right afcenfion,

77. If a, be the apparent place of a planet upon the meridian ZVW, when feen from the furface, and b, when viewed from the center of the earth, a b is its diurnal parallax in a vertical circle ZW to the horizon; but this fame circle is alfo a fecondary to the equator, whence there can be no parallax of right afcenfion.

Now suppose P the pole of VT, which is now called an arch of the ecliptic cutting the horizon WL in T, ZX a vertical circle, let RY be the planet's parallax, PRO a secondary of the ecliptic passing through the planet, when seen at R from the surface of the earth; PYQ another secondary,

fecondary, paffing through it, if it could be viewed from the earth's center, fo as to appear at Y; when at R, its latitude is R O, when at Y, its latitude is QY, the difference N Y, is the parallax of latitude.

78. When the planet appears at R in PRO, the fecondary of the ecliptic, the point O is its longitude from the first point of Aries; but when at Y in the fecondary PYQ, Q is the point of its longitude; whence the difference QO is the parallax of longitude.

But if the planet be in a vertical circle Z W, which paffes through P, the pole of the ecliptic, it can only have a parallax of latitude, and none of longitude. Let a b be the parallax of latitude; whence from either station, a b will be its parallax of latitude; and as there can pass but one fecondary through both, there can be no parallax of longitude.

The annual parallax of any heavenly body arifes from its being feen from the earth, when it is in different parts of its orbit.

D 4

The

# The refraction of the atmosphere.

79. If a ray of light enters a transparent medium obliquely, it does not pass ftraight on, but is bent at the point at which it enters: this bending is called refraction.

In fig. 19. AC represents the surface of the earth, T its center, BP a part of the atmosphere, HEK the sphere of the fixed stars, AF the sensible horizon, G a planet, GD a ray of light proceeding from G to D, where it enters our atmosphere, and is refracted towards the line DT, which is perpendicular to the furface of the atmofphere; and as the upper air is rarer than that near the earth, the ray is continually entering a denfer medium, and is every moment bent towards T, which caufes it to describe a curve, as DA, and to enter a spectator's eye at A, as if it came from E, a point above G. And as an object always appears in that line in which it enters the eye, the planet will appear at E, higher than its true place, and fiequently above the horizon AF, when its true place is below it at G. The

The greatest refraction is when the planet, &c. is feen in the horizon, being 33 min. When its altitude is 20 deg. the refraction is 2 m. 14 fec: at 40 deg. of altitude it is 58 fec: at 60 deg. of altitude it is 29 fec. and fo becomes infenfible, as the altitude increases.

### Solar and lunar eclipfes.

80. An eclipfe is a deficiency of light in the heavenly bodies. In an eclipfe of the fun, its light is intercepted from the fight of the inhabitants of any part of the earth, by the moon paffing between them and the fun; and as its difc is either partly, or wholly covered, it is called a partial or total eclipfe.

An eclipfe of the moon is caufed by her paffing through the shadow of the earth, whereby she is deprived of the surface light.

The fun can never be eclipfed but at the time of New Moon; neither can there be an eclipfe of the moon, but at the time of the Full Moon: In the first case, the New Moon must be within 18 degrees, in the last, the Full Moon within 12 degrees, of one of her nodes.

Thefe

These luminaries are not eclipsed every New and Full Moon, because the moon's motion is not in the plane of the ecliptic, in which the sun and earth always are. Hence the moon's latitude is oftentimes so much increased at the time of the New Moon, that her shadow does not touch the earth; and at the time of Full Moon, such as frequently passes by the earth's shadow without entering into it: but when the moon's latitude is inconsiderable, which only happens when she is within the limits above mentioned, she then appears either in or near the ecliptic.

Let HG, fig. 20. represent the path of the moon EF, the plane of the ecliptic, in which the center of the earth's schadow always moves; N, the node of the moon's orbit; A, B, C, D, represents four places of the earth's schadow in the ecliptic: when her schadow is at A, and the moon passing by at I, she will not enter into the schadow; but when the Full Moon is nearer to the node at K, only part of her globe passes through the schadow B, and that part becomes dark: this is called a partial eclips. When the Full Moon is at M, sche enters into

into the shadow C; in passing through it, she becomes wholly darkened at L, and leaves the shadow at O. This is called a total eclipse: and when the moon's center passes through that of the shadow, which can only happen at the very time she is in the node at N, it is called a central eclipse.

We have not yet mentioned the atmofphere, which requires our confideration, while we are treating of lunar eclipfes; for the fhadow of the earth does not reach the moon. In fig. 21. T reprefents the earth, BCDBgf its atmosphere, AB, AB, rays proceeding from the fun at S, touching the atmosphere at B and B; these go ftraight on, and terminate the fhadow of the atmosphere at H. The moon is constantly enlightened by the fun's rays until she enters this shadow, when she becomes fainter, as she continues to move between ABH and ABH.

The rays which enter the atmosphere obliquely, are refracted, and bent into curves that touch the earth; all the light between F f and G g, is intercepted by the earth;

earth; and the rays CE, DE, terminate the earth's shadow.

The light between F f, and A B, is refracted by the atmosphere, and diffused between C E, and A B, and continued beyond E, the point of the earth's schadow: whence it is plain, that the light proceeding from the sum becomes continually weaker, the farther it is from the earth; so that the schadow of the atmosphere is but a weak light, and therefore the moon is visible in an eclipse.

The fhadow of the atmosphere is conical, because the diameter of the fun is greater than that of the earth. This cone does not reach so far as the planet Mars: but the diameter of the shadow, in the place where it cuts the moon's orbit, is not 4th less than the carth's diameter.

A folar eclipfe happens, when the New Moon is in or near the node. In fig. 22. S reprefents the fun, M the moon, her fhadow falling upon DC, a part of the earth's circumference, which is furrounded by a penumbra. Beyond A and F, the earth is illuminated by an entire hemifphere of

of the fun. As you move from A to C, or from F to D, the light is continually diminishing; and near C and D, the rays come to the earth only from a finall point of the fun's furface.

This diminished light, which furrounds the shadow every way, is called the penumbra. An observer at B or E, can only see half the fun's diameter, the rest being hidden by the interposition of the moon. If the observer moves from B to C, or from E to D, the fun will be more and more withdrawn from his sight, until it becomes wholly invisible in the shadow itself; whence it is plain, that there may be a folar eclipse, although the shadow of the moon does not touch the earth, if the penumbra comes to its surface.

When the moon's shadow falls upon the earth, it is called a total eclipse of the sun; if the penumbra only reaches the earth, it is called a partial eclipse of the sun: with respect to particular places, it is faid to be total where the shadow passes; central, where the center of the moon covers that of the sun; and partial, where the penumbra

### 46 A Comprehensive View, &c.

umbra only goes by, as it is represented in fig. 23.

The wider the fhadow CD, fig. 22. is, the longer the fun will be totally eclipfed, and a larger fpace of the earth will be under the fhadow; but its breadth will vary, as the diftance of the moon from the earth, and of the earth from the fun varies: for when the earth is *in peribelion*, and the moon *in apogee*, that is, at its greateft diftance from the earth, the fhadow of the moon does not reach the earth, and the moon does not cover the fun: this is called an annular eclipfe, as is reprefented in fig. 24.

THE

The New CELESTIAL GLOBE, As Improved and Constructed by GEO: ADAMS In Fleet Street LONDON.

#### THE

# **DESCRIPTION** and **USE**

OF THE NEW

CELESTIAL and TERRESTRIAL

# GLOBES.

F the periphery of a femi-circle be I turned round its diameter as an a globe or fphere, and the center of the femi-circle will be the center of the globe : it therefore follows, that as all the points in the circumference of the femi-circle, are at an equal diftance from its center, fo all the points of a globe, thus generated, must be the fame.

82. Any

### 48 Description and Use of the

82. Any straight line passing through the center of a globe, being terminated by its furface, is called a diameter; and that diameter about which the globe turns, is called its axis; the extremities of which are called the poles of the globe.

83. There are two artificial globes. That on which the furface of the earth is reprefented, is called the terrestrial globe.

84. The other on which the face of the ftarry fphere is delineated, is called the celeftial globe.

85. In the use of the terrestrial globe, we are to confider ourselves standing upon some part of its surface, and that its motion represents the real diurnal motion of the earth, which is from west to east.

86. In the use of the celestial globe, we are to suppose ourselves at the center, and that its motion represents the apparent diurnal motion of the heavens, which is from east to weft.

87. Note, The stars being delineated upon the convex surface of the celestial globe, we must suppose ourselves at the center: because under such a supposition they would appear,

### Celeftial and Terrestrial Globes.

appear, as they naturally do, in the concave furface of the heavens.

88. Several circles are defcribed upon the furface of each globe. Those whose planes pass through the center of the globe, are called great circles; some of which are graduated into 360 degrees, 90 of which make a quadrant.

89. Those circles whose planes do not pass through the center of the globe, are called leffer circles.

90. Our new terreftrial and celeftial globes, fig. 1, and fig. 25. are each of them fufpended at their poles in a ftrong brass circle NZÆSN, and turn therein upon two iron pins, which are the axis of the globe. They have each a thin brass femi-circle NHS moveable about the poles, with a fmall thin fliding circle thereon.

91. On the terrestrial globe, fig. 1. this femi-circle NHS is a moveable meridian, and its small sliding circle H, the visible horizon of any particular place to which it is set. But,

92. On the celeftial globe, fig. 25. this femi-circle NHS is a moveable circle of E decli-

E----

### 30 Description and Use of the

declination, and its finall circle H, an artificial fun or planet.

93. Each globe hath a brass wire circle, TWY, placed at the limits of the crepufculum, or twilight; which, together with the globe, is fet in a wooden frame : the upper part BC is covered with a broad paper circle, whose plane divides the globe into two hemispheres, and the whole is supported by a neat pillar and claw, with a magnetic needle in a compass box at M.

94. On our new terrestrial globe, the division of the face of the earth into land and water, is accurately laid down from the latest and best astronomical, geographical, and nautical discoveries. There are also many additional circles, as well as the rhomb-lines, for the greater ease and convenience in solving all the necessary geographical and nautical problems.

95. On the furface of our new celeftial globe, all the fouthern conftellations, lately observed at the Cape of Good-Hope by M. de la Caille, and all the stars in Mr. Flamsted's British catalogue, are accurately laid down, and marked with Greek and Roman letters of reference, in imitation of Bayer. Upon each

#### Celestial and Terrestrial Globes. 51-

each fide of the ecliptic are drawn eight parallel circles at the distance of one degree from each other, including a fpace of fixteen degrees, called the zodiac; thefe are croffed at right angles with fegments of great circles at every fifth degree of the ecliptic, for the readier noting the place of the moon or any planet upon the globe.

96. We have also inferted from Ulugh Beigh, printed at Oxford, A. D. 1665, the manazil al kamer, i. e. the manfions of the moon of the Arabian aftronomers; which are fo called, becaufe they observed the moon to be in or near one of these every night, during her monthly course round the earth, to each of which the Arabian characters are affixed. They may be of very great use to beginners to teach them the names of the flars, as well as to mariners for the fame purpofe; who may have occafion to observe the distance of the moon from a fixed star, in the new method of discovering the longitude at sea. They will likewife ferve to shew, how the moon passes from star to star in the course of one or feveral nights, which is a very curious and uleful amutement; and as they are a divifion

E 2

# 52 Description and Use of the

tion of the heavens different from any thing the Greeks were acquainted with, and therefore not borrowed from them, and as we do not know they were ever inferted on any globe before, we hope we have with propriety placed them on our new celeftial globe. See Coftard's Hift. of Aftronomy, p. 40.

# The broad paper circle BC on the furface of the wooden frame which fupports the brafs meridian

97. Contains four concentric circular ipaces. The innermost of which is divided into 360 degrees, and numbered into four quadrants, beginning at the east and west points, and proceeding each way to 90 degrees at the north and fouth. points; these are the four cardinal points of the horizon. The fecond circular space contains, at equal distances, the thirty-two points of the mariner's compais. Another circular space is divided into twelve equal parts, representing the twelve figns of the zodiac; these are again subdivided into 30 degrees each, between which are engraved their names and characters. This 000 fpace

### Celestial and Terrestrial Globes.

53

space is connected with a fourth, which contains the kalendar of months and days; each day, on the new eighteen-inch globes, being divided into four parts, expressing the four cardinal points of the day, according to the Julian reckoning; by which means the fun's place is very nearly obtained for the three common years after biffextile, and the intercalary day inferted without confusion. Whence we derive the following

### PROBLEM I.

# To find the fun's place any day in the year on the broad paper-circle.

98. Confider whether the year in which you feek the fun's place is biffextile, or the first, second, or third year after.

99. If it be the first year after bissextile, those divisions, to which the numbers for the days of the month are affixed, are the respective days for each month of that year at noon; opposite to which, in the circle of twelve figns, is the fun's place.

100. If it be the fecond year after biffextile, the first quarter of a day backwards, or towards the left hand, is the day of the month

E 3

### 34 Description and Use of the

month for that year; against which, as before, is the sun's place.

101. If it be the third year after biffextile, half a day backwards is the day of the month for that year, opposite to which is the sun's place.

102. If the year in which you feek the fun's place is biffextile, then three quarters of a day backwards is the day of the month from the 1ft of January to the 28th day of February inclusive. The intercalary, or 29th day, is three fourths of a day to the left hand from the 1ft of March; and the 1ft of March itself is one quarter of a day forward, from the division marked 1; and fo for every day in the remaining part of the leap-year; against each of which is found the fun's place.

In this manner the intercalary day is very well introduced every fourth year into the kalendar, and the fun's place very nearly obtained according to the Julian reckoning. Thus:

A. D	Sun's place, April 25							1 25.
1769.	first year	after biffext	tile	Ø	:	5°	:	211
1770.	fecond -			Q	:	5°	:	06'
1771.	third			Ø	:	4°	:	55
\$772.	bissextile			8	;	5°	:	35'
Dranis	I	E				-	C	)ne

### Celefial and Terrestrial Globes. 55

One use of the broad paper circle is to diffinguith the points of the horizon; in this case it represents the rational horizon of any particular place, which is an imaginary great circle in the sphere of the heavens, dividing the visible from the invisible hemitphere. This is supposed to be parallel to a leffer circle, called the sensible horizon, whose plane may be conceived to touch the sufface of the globe at that place upon which an observer stands, and to terminate his sight when he views the heavens round about. The extent of the sensible or visible horizon is greater or less, as we stand higher or lower.

103. Another use we shall make of this circle is to represent the circle of illumination, or that circle which separates day from night.

A third use to which this circle may be applied, is to represent the plane of the ecliptic. All of which shall be illustrated in their proper places.

In all politions of the celeftial globe, this broad paper furface is the plane of the horizon, and diftinguishes the visible from the invisible part of the heavens.

E 4

Note,

### Description and Use of the

56

Note, As this circle occafionally reprefents various great circles of the fphere, we have given it the name of broad paper circle, to prevent the reader from confidering it as an horizon, when it really reprefents the plane of the earth's illuminated difc, &c.

The north-fide of the wooden frame ought to be placed directly towards the north-fide of the heavens, which is readily done by the mariner's compass under our new globes.

# The ftrong brass circle, or meridian, NZÆSN.

104. There are two notches in the broad wooden circle (art. 97.) upon the plane of which the broad paper circle is placed, which receive the strong brass circle: the body of the globe, being suspended at two opposite points in this circle, turns round therein on its iron poles, one of which N represents the north, and the other S the south pole.

105. One fide of this strong brass circle is graduated into four quadrants, each containing 90 degrees. The numbers on two of these quadrants increase from the equator Celestial and Terrestrial Globes. 57

tor towards the poles; the numbers on the other two increase from the poles towards the equator.

"The reafon why two quadrants of the meridian are numbered from the equator, and the other two from the poles, is becaufe the first of these two shew the distance of any point on the globe from the equator or equinoctial, and the other ferves to elevate the globe to the latitude of any place."

106. The ftrong brass circle of the celestial globe is called the meridian, because the fun's center is directly opposite thereto at noon.

107. On the ftrong brass circle of our new terrestrial globe, and about  $23\frac{1}{2}$  degrees on each fide of the north pole, the days of each month are laid down according to the fun's declination. If any day of the month is placed in the plane of the horizon, it will shew the fun's declination for that day upon the other fide of the brass meridian; and this brass circle is fo contrived, that the globe may be placed in the position of a direct or right sphere, (which is, when the north and south poles are placed in
in the plane of the broad paper circle) and also that the fouth pole may be elevated above the plane of the broad paper furface, with as much ease as the north pole. A circumstance which we thought not unworthy of our attention in the construction of our new globes.

108. The graduated fide of the ftrong brass circle, encompassing our new terrestrial globe, faces the west; being most agreeable to the real diurnal motion of the earth, which is from west to east.

109. But that which furrounds the celeftial globe, faces the eaft, as the apparent diurnal motion of the heavens is from eaft to weft.

110. In all inclinations of either globe, the north pole should be directed towards the north point of the heavens, which the mariner's compass at M, placed under each of the globes, will enable us to do with the greatest readines,

### The horary circle.

111. We use no other circle to measure the hours and minutes of time, but the equator,

equator, upon the furface of either globe; it being not only the molt natural, but the largest circle that can possibly be applied for that purpose. This is done by a semi-circular wire ÆF placed in the plane of the equator, carrying two indices; one of which 1 is occasionally to be used to point out the time.

As the first meridian in our new globes passes through London, it therefore becomes the XII o'clock hour circle; and this falls upon the intersection of the equator and ecliptic at the first point of Aries; the other XIIth hour circle passes through the opposite intersection at the first point of Libra.

Remember, when the globe shall be hereafter rectified for London, or any other place, on the same meridian with t, that then the graduated side of the strong brass meridian is the horary index itself.

It may happen, that the globe fhall be for rectified, as that the two points of XII o'clock will fall in, or to near, the east and west points of the broad paper circle, that neither of the horary indices can be applied thereto 3 in

60

in fuch a cafe either of these points themfelves will be the horary index.

112. The hours and minutes are graduated below the degrees of the equator on either globe; and as

113. The motion of the terrestrial globe is from west to east, the horary numbers increase according to the direction of that motion.

114. The motion of the celestial globe being from east to west, the horary numbers increase in that direction.

### The thin brass semi-circle NHS.

115. This turns upon the poles of the globe, and may be called a proper or a moveable meridian. It is graduated each way to 90 degrees from the equator to either pole.

116. To this femi-circle on the new celeftial globe, fig. 25. is fitted a fmall thin brafs circle H, about half an inch diameter, which flides from pole to pole; when we confider the fun's apparent diurnal motion, we call it an artificial fun.

117. But to the thin femi-circle applied to the new terrestrial globe, fig. 1, is fitted a fmall

finall thin circle H, about two inches diameter, that flides from pole to pole; which is divided into a few of the points of the mariner's compass, and is called a terrestrial or visible horizon.

# The brafs quadrant of altitude Z A

118. Is a thin narrow flexible flip of brafs, that will bend to the furface of the globe; it has a nut with a fiducial line upon it, which may be readily applied to the divisions on the ftrong brass meridian of either globe; one of its edges is graduated into 90 degrees, and continued to 20 degrees below the horizon. Upon the terrestrial globe, its use is to shew the distance of places; and when applied to the celeftial globe, it shews the diftance between two ftars. If fixed to the zenith or pole of the horizon, it flews the altitude of any point upon the globe, its graduations being numbered upwards from the horizon to 90 degrees, and downwards to 20 degrees for the depression of any celestial object. It will represent any vertical circle paffing through the pole of the horizon, in its motion round the zenith point, as well as the prime vertical, which passes through

through the east and west points of the horizon. Upon both globes it occasionally shews the distance of every secondary to the horizon; and has other uses, which will be hereafter shewn.

119. Note, When we speak of bringing any point or place to the strong brass meridian, we mean that it should be brought to its graduated side, which is properly the meridian.

Alfo, when we fpeak of bringing the moveable meridian, quadrant of altitude, or any other thin flexible circle, to any point or place ; we mean that their graduated edges flould be brought to that point, or place.

Of the feveral circles defcribed upon the furface of each globe.

120. We may imagine as many as we pleafe upon the furface of the earth, and conceive them to be extended to the fphere of the heavens, marking thereon concentric circles.

121. The planes of all great circles pass through the center, and divide the globe into two equal hemispheres: a small circle divides the surface of a globe into two unequal parts;

parts; all circles are supposed to be divided into 360 degrees.

We shall begin with the description of the equator, this being the most eminent great circle on either globe.

### The equator or equinoctial ÆIQ

122. Is 90 degrees diftant from the, two poles of the globe; and is fo called, because when the sun appears to pass vertically over this circle, the days and nights are of an equal length to all the inhabitants of the earth.

123. The plane of the equator passes through the middle of the globe at right angles to the polar axis.

On our new globes it is graduated into 360 degrees; upon the terrestrial globe, the numbers increase from the meridian of London westward, and proceed quite round to 260.

124. They are also numbered from the fame meridian eastward by an upper row of figures, for the ease of those who use the English tables of the latitude and longitude of places.

125. On

125. On our new celestial globes the: equatorial degrees are numbered from the. first point of Aries eastward, to 360 degrees.

126. Close under the degrees, on either globe, is graduated a circle of hours and minutes.

127. On the celestial globe, the hours increase eastward from Aries to XII at Libra, where they begin again in the same direction, and proceed to XII at Aries.

128. But the horary numbers under the equator of the terrestrial globe, increase by twice twelve hours westward, from the meridian of London, to the same again.

129. In every polition of the globe, except that of a parallel sphere, the plane of the equator cuts the eastern and western points of the broad paper circle, when confidered either as an horizon, the ecliptic, or circle of illumination.

And as the globe is turned about, it always keeps to one point of the ftrong brafs circle, in which, as hath been obferved, the degrees are numbered both ways from the equator, that the diftance of latitude north or fouth of any point on the furface of the

the globe may be more eafily computed. Whence arifes the following

# PROBLEM II.

# To find the latitude of a place.

and Rome, fud

1 30. Bring the place to the graduated fide of the ftrong brass meridian; the degree it then cuts shews its distances from the equator, which on the terrestrial globe is called latitude.

Thus London has 31 deg. 32 min. of north latitude; Constantinople, 41 deg. of north latitude; Quebec, in Canada, 46 deg. 55 min. of north latitude; and the Cape of Good Hope, 34 deg. fouth latitude.

# PROBLEM III.

To find all those places which have the fame latitude with any given place.

<sup>1</sup>31. Suppose the given place London; turn the globe round, and all those places which pass under the same point of the strong brass meridian, are in the same latitude.

F

## PROBLEM IV.

## To find the difference of latitude between any two places.

132. Suppose London and Rome, find the latitude of each place by prob. ii. art. 130. Their difference is the answer.

### PROBLEM V.

### To find the declination of the fun.

133. First, On either globe for the fun's declination, find his place in the ecliptic by prob. i. art. 98, &c. Then bring that point of the ecliptic line upon the globe under the strong brass meridian, and the degree which it cuts is the fun's declination for that day. Or,

Upon the terrestrial globe, that parallel which passes through the point of the ecliptic answering to the day of the month, will shew the fun's declination, counting the number of parallels from the equator, Alfo;

PROBLEM

On

On the celeftial globe, feek the day of the month clofe under the ecliptic line itfelf, againft which is the fun's place; bring that point under the ftrong brass meridian, and the degree that stands over it is the fun's declination for that day. Thus on the 23d of May the fun's declination will be about 20 deg. 10 min. and upon the 23d of August it will be 11 deg. 13 min.

### For the declination of any far.

134. Secondly, Bring the ftar to the ftrong brafs meridian on the celeftial globe, and the degree it ftands under is its diftance from the equator, and this diftance is called the ftar's declination, which may be either north or fouth, according to the fide of the equator on which the ftar is fituated.

Thus the declination of the ftar Arcturus, marked  $\alpha$  in the conftellation Bootes, has about 20 deg. 30 min. north declination; and that of Syrius in Canis Major, or the Dog-ftar, marked  $\alpha$ , has about 16 deg. 30 min. fouth declination.

135. Hence we fee, that the latitude of places on the earth, and the declination of  $F_2$  the

67

the fun and stars, &c. in the heavens, have but one idea, the meaning of which is no more than their distance (either of places on the terrestrial, or of the luminaries in the celestial spheres) from the equator.

The declination of a fixed ftar always continues the fame, but that of the fun, moon, and planets, varies.

1 36. Those stars, whose declinations are equal to the latitude of any place upon the earth, are called correspondents to that place; and pass once in every 24 hours vertically to the inhabitants of such latitude : that is, those stars appear in their zenith, or are directly over their heads. Hence the following

#### PROBLEM VI.

To find what ftars pass over or nearly over the zenith of any place.

137. Find the latitude of the place by prob. ii. art. 98. upon the terrestrial globe, which is the distance of that place from the equator; then turning the celestial globe, all those stars which pass under the strong brass meridian at the same distance from the equator, will pass directly over the heads

of those inhabitants, and therefore become celeftial correspondents to all those who live under the fame parallel of latitude.

Thus the ftar marked y of the fecond magnitude in the head of the dragon is 51 deg. 32 min. distant from the celestial equator, fo alfo is London at the fame diftance from the terrestrial equator: therefore the declination of this star is equal to the latitude of London, and confequently it becomes our celeftial correspondent.

The ftar marked a of the fecond magnitude in Perfeus's fide, called Algenib, paffes over the zenith of those inhabitants in France who live 14 min. of one degree fouth of Paris; it also passes nearly over the zenith of St. George's Bay in Newfoundland.

### Celestial and terrestrial meridians 1400. All those halfees of great circles, that

Whence we call it a inoveable mendian,

-n 1.38. Are great circles drawn upon the globes from one pole to the other, and crofling the equator at right angles. Upon Our new terrestrial globe there are twentyfour of these meridians, which are also hourcircles, being 15 degrees from each other. Thus 15 degrees on the equator is equal to F 2 one

70

one hour, and each fingle degree equal to four minutes of time. Only four meridians which are also called colures, are drawn upon the furface of the celestial globe.

139. There are no places on the furface of the earth, or fpaces in the apparent fphere of the heavens, through which, meridians may not be conceived to pafs; confequent= ly all points on the terrestrial or celestial fpheres have their meridians. So that they only (properly speaking) live under the same meridian, that are under the fame semi-circle, on the fame fide of the poles.

This variety of meridians on the globes is fupplied by the thin brass femi-circle, which being moveable about the poles, may be fet to every individual point of the equator. Whence we call it a moveable meridian, art. 115.

140. All those halves of great circles, that are drawn from pole to pole, are the meridians of those places through which they pass, and being perpendicular to the plane of the equator, are called secondaries thereto.

141. One of these meridians on our new terrestriat globe passes through London, and is called a first meridian; because from that point

#### Celeftial and Terrefinal Globes. 71

point which is marked v, where it croffes the equator, the degrees of longitude, as well as the hours and minutes of time, begin.

The opposite meridian to this croffes the great Pacifick Ocean, and paffes through the first point of Libra, marked = upon the globe.

This meridian is graduated from pole to pole, and its numbers increase from the equator each way to the pole. One particular use to which it may be applied, and for which it was at first defigned, is to folve fome of the cafes in spherical trigonometry with ease and propriety, as will be seen hereafter.

Some geographers make their first meridian pass through the ille of Fer, or Ferro.

#### PROBLEM VII.

the elobe callward, and the prices

### To find the longitude of a place.

142. The longitude of any place is that point or degree upon the equator, which is croffed by the meridian of that place, reckoned from a first meridian.

Bring the moveable meridian to the place, and that degree on the equator which it cuts, is

72

is its longitude from London, in degrees, and minutes, or that hour and minute is its longitude expressed in time.

Or if we bring the place to the ftrong brass meridian, that will cut the equator in the longitude as before.

Thus Bofton in New England is about 70½ degrees weft of London; Cape Comorin in the East Indics 282°. weft of London; or the longitude of the first place expressed in time is 4 h. 42 min. of the fecond 18 h. 48 min.

143. The method of reckoning longitude always weftward from the first meridian is most natural, because it is agreeable to the real motion of the earth;

But the common method is to reckon it half round the globe eaftward, and the other half weftward from the first meridian, ending either way at 180 degrees.

Thus Cape Comorin is 78 degrees east of London.

Note, The numbers neareft the equator increase westward from the meridian of London quite round the globe to 360, over which another set of numbers is engraved, which increase the contrary way, by which

which means the longitude may be reckoned upon the equator either east or west.

144. It is mid-day or noon to all places in the fame meridian at the fame time.

Thus London, Oran, Cape Coast-castle in the Mediterranean, and Mundfort on the Gold-coast, have their noon nearly at the fame time; Boston in New England about 4 h. 42 min. later; and Cape Comorin 18 h. 48 min. later.

145. The difference of longitude of any two places, is the quantity of an angle at the pole made by the meridians of those places; which angle is measured upon the equator.

# To express this angle upon the globe

146. Bring the moveable meridian to one of the places, and the other place under the ftrong brass circle, they then contain the required angle; the measure or quantity of which is the number of degrees counted on the equator between these two brass meridians.

total provide a state of the second state of t

benetico

# PROBLEM VIII.

To find what places have mid-day, or the fun, upon their meridian, at any given hour of the day in any place proposed.

147. First, Let the hour proposed be X o'clock in the morning at London.

As the real diurnal motion of the earth, here represented by the terrestrial globe, is from west to east,

All places to the eaftward of any particular meridian must necessarily pass by the fun, before the meridian of any other place to the westward of that particular meridian can arrive at it.

148. And therefore as the first meridian on our new terrestrial globe passes through London, if the proposed place be London, as in this case, bring the given hour, which is placed on our globes, to the east of London if it be in the morning, but to the west of London if it be in the asternoon, to the graduated fide of the strong brass meridian; and all those places which lie directly under it,

it, have noon, or the fun, upon their meridian, when it is X o'clock at London.

Thus having brought the Xth hour on the equator to the eaftward of Löndon under the divided fide of the firing brafs meridian, it will be found to pais over the eaftern fide of Lapland, and the eaftern extremity of the gulf of Finland; Peterfburgh in Ruflia, to crofs a part of Moldavia and the Black Sea, thence it paffes over a part of Turky, and goes between the iflands of Candia and Cyprus in the Mediterranean, thence over the middle of Egypt through the eaftern fide of Africa, and acrofs the bay of Lorenzo; all which places have the fun on their meridian when it is X o'clock in the morning at London.

149. Secondly, Let the hour proposed be IV o'clock in the afternoon at Port-Royal in Jamaica.

Bring Port-Royal in Jamaica to the ftrong brafs meridian, and fet the horary index to that XII which is most elevated; then turn the globe from west to east, until the horary index points to IV o'clock, and the strong brafs meridian will pass over the western side of the isle Pasares in the Pacific Ocean, and

and the eastern fide of the isle La Messa, thence it crosses the equator, and passes nearly over the islands Mendoca and Dominica, which places have the sun on their meridian when it is IV o'clock in the afternoon at Port-Royal in Jamaica.

150. Thirdly, Let the proposed hour be go min. past V o'clock in the morning at Cape Pasaro in the island of Sicily.

Bring Cape Pafaro to the ftrong brafs meridian, fet the horary index to that XII which is most elevated, and turn the globe westward, because the proposed time is in the morning, till the horary index points to 5 h. 30 min. and you'll find the strong brafs meridian to pass over the middle of Siberia, Chinese Tartary, the kingdom of China, Canton in China, the middle of the island of Borneo, &c. at all which places it is noon, (they having the fun upon their meridian at the same time) when it is half an hour past V o'clock in the morning at Cape Pasaro in Sicily.

the globe frum well to call, until the honey index points to IV o'cl etc. and the theory

### PROBLEM IX.

# To find what hour it is at any place proposed when it is noon at any given place.

<sup>1</sup> 151. Bring the proposed place under the ftrong brass meridian, and fet the horary index to XII, then turning the globe, bring the given place to the meridian, and the hour required will be shewn by the horary index upon the equator. If the proposed place be to the eastward of the given place, the answer will be asternoon; but if to the westward of it, the answer is before noon.

Thus when it is noon at London, it is 49 minutes past XII at Rome, and 32 minutes past VII in the evening at Canton in China, and also 15 minutes past VII o'clock in the morning at Quebec in Canada, and this at one and the fame instant of time.

RED BE RED

### 78 Defeription and Ufe of the

### PROBLEM X.

At any given time of the day in the place where you are, to find the hour at any other place proposed.

152. Bring the proposed place under the ftrong brass meridian, and set the horary index to the given time; then turn the globe till the place where you are is under the brass meridian, and the horary index will point to the hour and minute required.

Thus suppose we are at London at IX o'clock in the morning, what time of the day is it then at Canton in China? Answer, 31 minutes past IV in the asternoon.

Also, when it is IX in the evening at London, it is about 15 minutes pass IV o'clock in the afternoon at Quebec in Canada.

121020

# PROBLEM XI.

The latitude and longitude of any place being known, to find that place upon the globe; or if it be not inferted, to find its place, and fix the center of the artificial horizon thereon.

153. The latitude of Smyrna in Afia is 38 deg. 28 min. north, its longitude 27 deg. 30 min. east of London.

Bring 27 deg. 30 min. on the equator counted eaftward of our first meridian to the strong brass circle, and under 38 deg. 28 min. on the north side of the equator, you will find Smyrna.

The latitude of Cape Lorenzo in Peru is 1 deg. 2 min. fouth, and longitude 80 deg. 17 min. weft of London: this place is not inferted upon the globe. Therefore bring the graduated edge of the moveable meridian to 80 deg. 17 min. counted weftward on the equator, and flide the diameter of the artificial horizon to 1 deg. 2 min. fouth; and its center will be correctly placed on that

that point of the globe, where the Cape of Lorenzo ought to have been placed.

The four last problems depend entirely on the knowledge of the longitude and difference of longitude of places.

# The ecliptic EL

154. Is that graduated circle which croffes the equator in an angle of about  $23\frac{1}{2}$  degrees; and this angle is called the obliquity of the ecliptic.

This circle is divided into 12 equal parts, each of which contains 30 degrees; the beginning of each 12th part is marked with the ufual characters, which with their names are as follow:

T 2 3 4 6 Aries, Taurus, Gemini, Cancer, Leo, Virgo, Libra, rons a R -----7 8 . 9 10. II Scorpio, Sagittarius, Capricornus, Aquarius, Pisces. in z vs X. By these the twelve figns are represented upon the terrestrial globe. Upon our celeftial globe, just under the ecliptic, the months, and days of each month, are graduated,

duated, for the ready fixing the artificial fun upon its place in the ecliptic.

The fun's apparent place is always in this circle; he advances therein every day about 59 min. 8 fec. of one degree, and feems to pais through it in a tropical year.

155. Those two points, where the ecliptic crosses the equator, are called equinoctial points, and are marked with these characters  $\gamma$  and  $\Rightarrow$  at the beginning of Aries and Libra.

The first of these is called the vernal, the fecond the autumnal, equinox.

156. The first degree of Cancer and Capricorn is marked with the characters 5 and  $\sqrt{5}$ , which two points are called the folftices; the first is the fummer folftice, the fecond that of the winter, to all inhabitants upon the north fide of the equator; but directly contrary to those on the fouth fide of it.

Although the ecliptic does not properly belong to the earth, yet we have placed it upon our terreftrial globe according to ancient cuftom; it being useful in some particular cases; it is chiefly to be regarded upon the celeftial globe.

G

11 E -

2721

157. The

82

157. The longitude of the ftars and planets is reckoned upon the ecliptic; the numbers beginning at the first point of aries  $\Upsilon$ , where the ecliptic crosses the equator, and increasing according to the order of the figns.

158. The latitude of the ftars and planets is determined by their diftance from the ecliptic upon a fecondary or great circle paffing through its poles, and croffing it at right angles.

159. Twenty-four of these circular lines, which cross the ecliptic at right angles, being fifteen degrees from each other, are drawn upon the surface of our celestial globe; which being produced both ways, those on one side meet in a point on the northern polar circle, and those on the other meet in a point on the southern polar circle.

160. The points determined by the meeting of these circles are called the poles of the ecliptic, one north, the other south.

161. The longitude of the stars hath been observed to increase about a degree in 72 years, which is called the precession of the equinox.

The

The celeftial figns and conftellations

162. On the furface of the celestial globe are represented by a variety of human and other figures, to which the stars that are either in or near them, are referred.

The feveral fystems of stars, which are applied to those images, are called constellations. Twelve of these are represented on the ecliptic circle, and extend both northward and southward from it. So many of those stars as fall within the limits of 8 degrees on both sides of the ecliptic circle, together with such parts of their images as are contained within the aforesaid bounds, constitute a kind of broad hoop, belt, or girdle, which is called the zodiac.

The names and the refpective characters of the twelve figns of the ecliptic may be learned by infpection on the furface of the broad paper circle; and the conftellations from the globe itfelf.

163. The zodiac is represented by eight circles parallel to the ecliptic, on each fide thereof; these circles are one degree distant  $G_2$  from

from each other, fo that the whole breadtly of the zodiac is 16 degrees.

164. Amongst these parallels, the latitude of the planets is reckoned; and in their apparent motion they never exceed the limits of the zodiac.

165. On each fide of the zodiac, as was observed, other constellations are distinguished; those on the north fide are called northern, and those on the south fide of it, southern constellations.

166. All the stars which compose these constellations, are supposed to increase their' longitude continually; upon which supposition, the whole starry firmament has a flow motion from west to east; infomuch that the first star in the constellation of Aries, which appeared in the vernal intersection of the equator and ecliptic in the time of Meton the Athenian, upwards of 1900 years ago, is now removed about 30 degrees from it.

To represent this motion upon the celess globe, elevate the north pole, fo that its axis may be perpendicular to the plane of the broad paper circle, and the equator will then be in the same plane; let these reprefent

fent the ecliptic, and then the poles of the globe will alfo reprefent those of the ecliptic; the ecliptic line upon the globe will at the fame time represent the equator, inclined in an angle of  $23\frac{1}{2}$  degrees to the broad paper circle, now called the ecliptic, and cutting it in two points, which are called the equinoctial intersections.

Now if you turn the globe flowly round upon its axis from eaft to weft, while it is in this polition, there points of interfection will move round the fame way; and the inchination of the circle, which in flowing this motion reprefents the equinoctial, will not be altered by fuch a revolution of the interfecting or equinoctial points. This motion is called the preceffion of the equinoxes, because it carries the equinoctial points backwards amongs the fixed stars.

The poles of the world feem to defcribe a circle from eaft to weft, round the poles of the ecliptic, arifing from the precefiion of the equinox. This motion of the poles is eafily reprefented by the above position of the globe, in which, if the reader remembers, the broad paper circle reprefents the ecliptic, and the axis of the  $G_{2}$  globe

85

globe being perpendicular thereto reprefents the axis of the ecliptic; and the two points, where the circular lines meet, described in art. 150, 160. will now represent the poles of the world, whence as the globe si flowly turned from east to west, these points will revolve the fame way about the poles of the globe, which are here fupposed to represent the poles of the ecliptic. The axis of the world may revolve as above, although its fituation with respect to the ecliptic be not altered; for the points here supposed to reprefent the poles of the world, will always keep the fame diftance from the broad paper circle, which represents the ecliptic in this fituation of the globe \*.

167. From the different degrees of brightnefs in the ftars, some appear to be greater than others, or nearer to us: on our celessial globe, they are diffinguished into seven different magnitudes.

### General phœnomena arifing from the earth's diurnal motion.

168. The daily rotation of the earth about , its axis is one of the most effential points which

• RUTHERFORTH'S Syllem of Nat. Phil. vol. II. p. 730.

which a beginner ought to have in view; for every particular meridian thereon is fucceffively turned towards every point in the heavens, and as it were defcribes circles in the celeftial fphere, perpendicular to the axis of the earth, and parallel to each other; by which means the fixed ftars feem to have an apparent diurnal motion.

169. Except those two points in the starry firmament, into which the earth's axis, supposed to be so far extended, would fall; these two points are called the celessial poles, which correspond with our terrestrial north and south poles.

170. We have fo contrived our new globes that the real diurnal motion of the earth and the apparent diurnal motion of the heavens are reprefented by them, art. 85, 86. and thence all problems folved as readily in fouth as in north latitudes, and in places on or near the equator: by which means we are enabled to thew, how the viciflitude of days and nights, their various alterations in length, the duration of the twilight, &cc. are really made by the earth's daily motion, upon the principles of the Pythagorean or Copernican fystem.

G 4

In

In fig. 26. E NQSE represent the apparent concave fphere of the fixed ftars, ænqsæ the globe of the earth, whole axis ns is supposed to be extended to NS, in the sphere of the fixed stars; all the stars seem to revolve upon these two points as poles.

If the plane of the earth's equator  $\mathfrak{Z} \simeq \mathfrak{Z} \simeq \mathfrak{Z}$ is conceived to be extended to the flarry firmament, it will point out the celeftial equator  $\mathfrak{E} \simeq \mathfrak{Q} \Upsilon \mathfrak{E}$ .

N represents the celestial, and n the terrestrial north pole, S and s the south pole.

## Parallels of latitude, declination, tropics and polar circles.

171. Fig. 26. That circle which any ftar feems to defcribe in twenty-four hours, is called its parallel: thus, suppose a right line drawn from C the center of the earth, through any point d of its surface, and extended to D in the starry firmament, by means of the earth's daily rotative motion, the extremity D of the line CD will defcribe the celessial parallel G x D x G, corresponding to the terrestrial parallel g d, of the

the point d. If DC be supposed to be extended to H, the opposite side of the starry firmament, it will describe another parallel equal to the former.

Those circular lines upon the terrestrial globes, which are described from the poles, on either fide of the equator, are parallel to it, and are called parallels of latitude, but on the celessial globe they are called parallels of declination.

There are four principal leffer circles parallel to the equator, which divide the globe into five unequal parts called zones; thefe are the two tropics, and the two polar circles.

We have already shewn, that the diftance of any parallel from the equator, measured in the arch of a great circle on the terrestrial sphere, is its latitude; and on the celessial sphere, its declination, art. 135.

172. If the fun, moon, a fixed flar, or planet, is fituated in any parallel between the equator Æ Q, fig. 26. and the north pole N, it is faid to have north declination; but if towards the fouth pole S, fouth declination.

Thus

Thus the two parallels G D, and H I, have the fame declination : because they are equally distant from EQ the equator; the first hath north, the last south declination.

Hence we must observe, that a celestial parallel G X D, and its correspondent g x d upon the earth, are two parallel circles, being fimilar elements of a cone, whose axis is that of the earth, and apex C, the center of the earth. Therefore the plane of a terrestrial parallel cannot be the same with its correspondent celestial parallel; only the plane of the celestial equator E = Q T E, is the same with that of the terrestrial æ z q, because these two planes are produced by the same radius C Q, perpendicular to the axis N S, on which the earth or the heavens are supposed to turn.

If by the earth's daily rotative motion, a ftar D paffes over the zenith d of any inhabitant of the earth, that ftar is the celeftial parallel, which corresponds to the terrestrial parallel of the observer; for the distance of the celessial parallel G D, contains the same number of degrees from Æ Q the celessial equator, as that of the inhabitant's parallel

parallel g d does from æq the terrestrial equator.

Therefore the measure of the arch of any inhabitant's distance from the terrestrial equator, which is called the latitude of the place, is fimilar and equal in the number of degrees, to that fixed star's declination, which passes over his zenith.

If the inhabitant changes his fituation either north or fouth, the different declinations of those stars which pass over his zenith, at the several places of his removal, will shew his advance towards or regress from the equator.

Whence any place upon the earth may be reprefented by its corresponding zenith point, in the apparent concavity of the starry sphere; as shall be hereafter shewn.

173. Upon our new terreftrial globe, there are twenty-three parallels drawn at the diftance of one degree from each other, on both fides the equator; which, with two other parallels at  $23\frac{1}{2}$  degrees diftance, include the ecliptic circle; these two are called the tropics. That on the north fide of the equator is called the tropic of Cancer; and the

the other, which is on the fouth fide of it, the tropic of Capricorn.

174. The fpace between these two tropics, which contains about 47 degrees, was called by the ancients, the torrid zone.

The two polar circles are placed at the fame diftance from the poles, that the two tropics are from the equator.

One of these is called the northern, the other the southern polar circle.

These include  $23\frac{1}{2}$  degrees on each fide of their respective poles, and consequently contain 47 degrees, equal to the number of degrees included between the tropics.

175. The fpace contained within the northern polar circle, was by the ancients called the north frigid zone, and that within the fouthern polar circle, the fouth frigid zone.

176. The spaces between either polar circle, and its nearest tropic, which contain about 43 degrees each, were called by the ancients the two temperate zones.

177. Whenever any parallel passes through two places on the terrestrial globe, these places have the same latitude.

Also all those stars which are in the fame parallel upon the celestial globe, have the fame declination.

And as the ecliptic is inclined to the equator in an angle of  $23\frac{1}{2}$  degrees, and is included between the tropics, every parallel in the tortid zone muft neceffarily crofs the ecliptic in two places; which two points fhew the fun's place, when he is vertical to the inhabitants of that parallel; and the days of the month upon the broad paper circle anfwering to those points of the ecliptic, are the days on which the fun passes directly over their heads at noon, and are called their two midfummer days: whence the inhabitants of the torrid zone have two fummers and two winters every year.

Hence as the earth's progreflive, or rather apparent annual motion, feems to be in the celeftial ecliptic, the fun's declination is thereby changed gradually every day. Therefore on our new terreftrial globe, as mentioned in art. 173. we have drawn parallels thro' the whole fpace of the torrid zone, and the two fpaces within the polar circles, to give a general and clear idea of the fun's apparent paffage from one tropic to the other.

The
94

# The colures

178. Are circular lines drawn on the celeftial globe from pole to pole, (as meridians are upon the terreftrial globe) croffing the equator at right angles, and being fecondaries to it. Art. 140.

179. The two celeftial meridians which pass thro' the first point of  $\gamma$  and  $\simeq$  making together one great circle, are represented by the circle  $B \gamma K \simeq B$ , in fig. 26. and are called the equinoctial colure. The points marked  $\gamma$  and  $\simeq$  are called the equinoxes, or equinoctial points.

180. The two ccleftial meridians reprefented by the circle N Æ S Q N, paffing through the folftitial points (marked 55 and vs) of Cancer and Capricorn, are called the folftitial colure.

181. These colures cut each other at right angles in the poles of the world, and divide the celestial equator, ecliptic, and zodiac into four equal parts, which points determine the four seafons of the year. See art. 34 to 41. and art. 187.

The

The equinoctial colure only passes through the poles of the world at n and s. But,

The folfitial colure paffes through the poles of the world at n and s, and alfo through the poles of the ecliptic at B and K, fig. 26.

Whence it happens in every daily rotation of the carth about its axis, that the folfiitial and equinoctial coloures are twice blended with every meridian upon the furface of the earth : confequently, each pole of the ecliptic appears to pafs, once every day, over all the meridians of the terrestrial fphere.

182. All those circular lines that are, or may be supposed, drawn on the celessial globe, which pass through the poles, cutting the equator at right angles, are called circles of declination; because the declination of those points or stars through which they pass, or the distance of those stars from the equator, is measured upon these circles: and this is done by bringing the divided edge of the moveable meridian to any star.

Hence the thin brass femi-circle, art. 115; which we call the moveable meridian, is also a moveable circle of declination.

Arctic

Arctic and antarctic circles, or circles of perpetual apparition and occultation.

183. The largest parallel of latitude on the terrestrial globe, as well as the largest circle of declination on the celestial, that appears entire above the horizon of any place in north latitude, was called by the ancients the arctic circle, or circle of perpetual apparition.

Between the arctic circle and the north pole in the celestial sphere, are contained all those stars which never set at that place, and seem to us, by the rotative motion of the earth, to be perpetually carried round above our horizon in circles parallel to the equator.

The largeft parallel of latitude on the terreftrial, and the largeft parallel of declination on the celeftial globe, which is entirely hid below the horizon of any place, were by the ancients called the antarctic circle, or circle of perpetual occultation.

This circle includes all the flars which never rife in that place to an inhabitant of

of the northern hemisphere, but are perpetually below the horizon.

All arctic circles touch their horizons in the north point, and all antarctic circles touch their horizons in the fouth point; which point, in the terrestrial and celestial spheres, is the intersection of the meridian and horizon.

If the elevation of the pole be 45 degrees, the most elevated part either of the arctic or antarctic circle, will be in the zenith of the place.

If the pole's elevation be lefs than 45 degrees, the zenith point of those places will fall without its arctic or antarctic circle. If greater, it will fall within.

Therefore the nearer any place is to the equator, the leffer will its arctic and antarctic circles be; and on the contrary, the farther any place is from the equator, the greater they are. So that,

At the poles, the equator may be confidered as both an arctic and antarctic circle, becaufe its plane is coincident with that of the horizon.

But at the equator (that is, in a right fphere) there is neither arctic nor antarctic circle.

They

They who live under the northern polar circle, have the tropic of Cancer for their arctic, and that of Capricorn for their antarctic circle.

And they who live on either tropic, have one of the polar circles for their arctic, and the other for their antarctic, circle.

Hence, whether these circles fall within or without the tropics, their distance from the zenith of any place is ever equal to the difference between the pole's elevation, and that of the equator above the horizon of that place.

From what has been faid, it is plain, there may be as many arctic and antarctic circles, as there are individual points upon any one meridian, between the north and fouth poles of the earth.

184. Many authors have miftaken these mutable circles, and have given their names to the immutable polar circles, which last are arctic and antarctic circles, in one particular case only, as has been shewn.

The

# The caufe of the daily change in the declination of the fun

185. Arifes from the earth's annual motion in the ecliptic, the inclination of its axis, and its always moving parallel to itfelf.

Imagine the plane of the earth's orbit extended as far as the fixed ftars, it will there mark out the circle  $\mathfrak{S}$ ,  $\mathfrak{P}$ ,  $\mathfrak{V}$ ,  $\mathfrak{V}$ ,  $\mathfrak{S}$ , which we call the celeftial ecliptic; fee fig. 26.

From this comparison of the earth's orbit with the celeftial ecliptic, is derived the ancient rule to find the fun's place, if we first find the earth's place, either by observation or calculation; fix figns added to or fubstracted from it gives the fun's true place in the ecliptic. Confequently it is the fame thing, when we confider the daily motion of the earth about her equatorial axis, represented by the terrestrial globe, whether we suppose the earth, or the fun, to have an annual motion.

It is also the fame thing in the use of the celestial globe, whether we suppose the earth to turn upon her equatorial axis, or H 2 the

99

the ftarry fphere to revolve upon the extremities of the fame axis extended to the heavens: the refult in either cafe will be the fame, provided we conceive ourfelves at the center of the globe.

186. We shall therefore suppose the sun's apparent annual motion to be in the plane of the celessial ecliptic, art. 34 to 41. and in his passage through it, describing by a ray connecting the centers of the carth and sun, a different circle of declination, parallel to the equator every day. Whereby all who inhabit any of those places on the earth which are situated between the terrestrial tropic of Cancer represented in s. 26. by s, e, and the terrestrial tropic of Capricorn represented by h, vs, have the sum at the time he is describing their parallel, in their zenith; or directly vertical, or over their heads, which happens twice every year.

187. Whence the inhabitants of those places, as well as mariners who pass between the tropics, have a corresponding zenith point, where their latitude is equal to the fun's parallel of declination, from the fun by day, and from the stars by night.

It

It is eafily conceived, that if the planes of the equator and ecliptic were united in one continued plane, a central folar ray, connecting the centers of the earth and fun, would by the earth's diurnal motion describe the equator every day; but, as we have before observed, the fun does apparently describe a different parallel every day: wherefore the ecliptic and equator are inclined to each other in an angle confirmed by observation of about 23 deg. 29 min.

Let the fun's apparent annual motion be represented by the circle  $\mathfrak{G}$ ,  $\simeq$ ,  $\Upsilon$ ,  $\mathfrak{G}$ , fig. 26, which bifects the celeftial equator  $\mathcal{I}_{\pm} = Q$  $\Upsilon$  Æ, in the points  $\Rightarrow$  and  $\Upsilon$ ; the first of thefe is called the autumnal, the fecond the vernal, equinoctial point.

When the fun is in a, he appears to defcribe the equator, at which time he has no declination; and as he proceeds gradually from = towards vs, his fouthern declination continually increases, and he describes less and less parallels, till he appears in vs, and describes the tropic of Capricorn; being, then at his greatest fouthern declination, viz. at his greatest diftance H 3

distance from the equator southerly, and also in the winter solftice.

In passing from vs to v, his declination decreases, and the parallels he describes are greater and greater, until he comes to Aries, or the vernal equinox, and again has no declination, describing the equator as before.

As he advances from thence towards 55, the declination increases, and the parallels described are less and less, until he arrives at 55, or the summer solftice; being then at his greatest northern declination, describing the tropic of Cancer.

Thence proceeding forwards towards  $\approx$ , the declination continually decreases, and the parallels described increase till the sun's arrival at the next succeeding autumnal equinox; where he again describes the equator, having no declination; and compleats the length of a mean solar tropical year, containing 365 d. 5 h. 49 min.

What we have faid with respect to fummer and winter folftices, is to be underflood with relation to those places which lie between the equator and the north pole; but

but to the places between the equator and fouth pole the contrary happens.

The two equinoxes are the fame to all the inhabitants of the earth.

We have been thus particular in our description of the sun's apparent annual motion, for the use of beginners; and we hope this confideration will plead in our behalf, if we should appear tedious or trifling to those who are masters of the subject.

But what has been faid, might yet be more clearly illustrated by an orrery or a tellurian, which shews the annual and diurnal motions of the earth, and parallelism of its axis, &cc. and by the different positions of the earth's axis, with respect to her enlightened dife; will make it appear to the eye as it is really understood by altronomers; and then we may with more propriety repair to the use of the globe utfelf.

## To supply the want of a tellurian

188. Deferibe a circle ABCD, fig. 8. with chalk upon the floor, as large as the room will admit of, that the globe may be moved round upon it: divide this circle H 4 into

into twelve parts, and mark them with the characters of the twelve figns, as they are engraved in fig. 8. or upon the broad paper circle; placing  $\mathfrak{D}$  at the north,  $v\mathfrak{s}$  at the fouth,  $\gamma$  in the eaft, and  $\mathfrak{A}$  in the weft: the mariner's compass under the globe will direct the fituation of these points, if the variation of the magnetic needle be attended to.

Note, At London the variation is between 20 and 21 degrees from the north westward.

Elevate the north pole of the globe, fo that  $66\frac{1}{4}$  degrees on the ftrong brass meridian may coincide with the furface of the broad paper circle, and this circle will then represent the plane of the ecliptic, as mentioned in article 103.

Set a final table or a ftool over the center of the chalked circle to reprefent the fun, and place the terreftrial globe upon its circumference over the point marked vs, with the north pole facing the imaginary fun, and the north end of the needle pointing to the variation : this is the position of the earth with respect to the fun at the time of the fummer folflice about the 21ft of June: and

and the earth's axis, by this rectification of the globe, is inclined to the plane of the large chalked circle, as well as to the plane of the broad paper circle, in an angle of  $23\frac{1}{4}$ degrees; a line or ftring paffing from the center of the imaginary fun to that of the globe, will reprefent a central folar ray connecting the centers of the earth and fun: this ray will fall upon the first point of Cancer, and defcribe that circle, shewing it to be the fun's place upon the terrestrial ecliptic, which is the fame as if the fun's place, by extending the ftring, was referred to the opposite fide of the chalked circle, here reprefenting the earth's path in the heavens.

If we conceive a plane to pass through the axis of the globe, it will also pass through the fun's center, and the points of Cancer and Capricorn in the terrestrial and celessial ecliptic; the central folar ray in this position of the earth is also in that plane; this can never happen but at the times of the folstice.

If another plane be conceived to pass through the center of the globe at right angles to the central folar ray, it will divide the globe into two hemispheres; that next the

the center of the chalked circle will reprefent the earth's illuminated difc, the contrary fide of the fame plane will at the fame time fhew the obfcure hemifphere.

The intelligent reader, for the use of his pupils, may realize this fecond plane by cutting away a femicircle from a fheet of card paste-board, with a radius of about 1+ tenth of an inch greater than that of the globe itself; if this plane be applied to  $66\frac{1}{2}$  degrees upon the strong brass meridian, it will be in the pole of the ecliptic; and in every fituation of the globe round the circumference of the chalked circle, it will afford a lively and lasting idea of the annual and diurnal motion of the earth, of the various phænomena ariling from the parallelism of the earth's axis, and in particular the daily change of the fun's declination, and the parallels thereby described.

Let the globe be removed from vs to m, and the needle pointing to the variation as before will preferve the parallelism of the earth's axis; then it will be plain, that the ftring or central folar ray will fall upon the first point of Leo, fix figns distant from, but opposite to the fign m, upon which the globe ftands:

1 ftands : the central folar ray will now de-1 fcribe the 20th parallel of north declination, 5 which will be about the 23d of July.

If the globe be moved in this manner from point to point round the circumference of the chalked circle, and care be taken at every removal that the north end of the magnetic needle, when fettled, points to the degree of the variation, the north pole of the globe will be obferved to recede from the line connecting the centers of the earth and fun, until the globe is placed upon the point Cancer : after which, it will at every removal tend more and more towards the faid line, till it comes to Capricorn again.

#### PROBLEM XII.

To rectify either globe to the latitude and horizon of any place.

189. If the place be in north latitude, raife the north pole; if in fouth latitude, raife the fouth pole, until the degree of the given latitude, reckoned on the ftrong brass meridian under the elevated pole, cuts the plane of the broad paper circle; then this circle

circle will represent the horizon of that place.

# To rectify for the fun's place.

190. After the former rectification, bring the degrees of the fun's place in the ecliptic line upon the globe to the ftrong brafs meridian, and fet the horary index to that XIIth hour upon the equator which is most elevated.

191. Or, if the fun's place is to be retained, to answer various conclusions, bring the graduated edge of the moveable meridian to the degree of the fun's place in the ecliptic, upon the celestial globe, and flide the wire which crosses the center of the artificial fun thereto: then bring its center, which is the intersection of the aforesaid wire, and graduated edge of the moveable meridian, under the strong brass meridian as before, and set the horary index to that XII on the equator which is most elevated.

transient maker the scienced path, some the

# To rectify for the zenith of any place.

192. After the first rectification, screw the nut of the quadrant of altitude so many degrees from the equator, reckoned on the strong brass meridian towards the elevated pole, as that pole is raised above the plane of the broad paper circle, and that point will represent the zenith of the place.

Note, The zenith and nadir are the poles of the horizon, the former being a point directly over our heads, and the latter, one directly under our feet.

193. If you are doubtful whether the proper point of the brafs meridian is correctly cut, when fet by the eye, apply a card cut in the fhape of fig. 27. to the place, flat upon the broad paper circle, and it will be truly adjusted.\*

If, when the globe is in this ftate, we look on the oppofite fide, the plane of the horizon will cut the ftrong brass meridian at the complement of the latitude, which is also the elevation of the equator above the horizon.

1

#### PROBLEM XIII.

To find the moon's mean place upon the celeftial globe, her age and day of the month being known.

194. The moon increases her longitude in the ecliptic every day about 13 deg. 10 min. by which means the croffes the meridian of any place about 50 minutes later than the did the preceding day.

Thus if her place be in the 12th degree of Taurus any day at noon, it will be 25 deg. 10 min. in Taurus on the fucceeding noon.

It is new moon when the fun and moon have the fame longitude, or are in or near the fame point of the ecliptic.

When they have opposite longitudes, or are in opposite points of the ecliptic, it is full moon. Art. 56 to 64.

To perform this problem tolerably near the truth, without having recourfe to an ephemeris, which may not always be at hand,

Find the day of the new moon next preceding the given day of the month in any common

common almanack, the number of days elapsed is the moon's age.

The equator on our new celeftial globe is divided by large dots into  $29\frac{1}{2}$  equal parts, each of which is directed by a fhort dotted line, to a number marked in Roman figures, expressing the feveral days of the moon's age.

# The rule.

195. Elevate the north pole of the celeftial globe to 90 degrees, and then the equator will be in the plane of, and coincide with the broad paper circle; bring the first point of Aries, marked  $\gamma$  on the globe, to the day of the new moon on the faid broad paper circle, which answers to the fun's place for that day; and the day of the moon's age will stand against the fign and degree of the moon's mean place; to which fet the artificial moon upon the ecliptic on the globe.

But if you are provided with an ephemeris \*, that will give the moon's latitude and place in the ecliptic; first note her place in the ecliptic upon the globe, and then counting

The Nautical Almanack is the best English Ephemeris extant.

counting fo many degrees amongst the parallels in the zodiac, either above or below. the ecliptic, as her latitude is north or fouth upon the given day, and that will be the point which represents the true place of the moon for that time, to which apply the artificial moon.

196. Note, The artificial moon is a fmall thin piece of brass in form of a crescent, having two holes a and b, fig. 28. through which a small string of filk twiss is put, that it may flip backwards or forwards upon it.

To one end c of this filk firing is tied a fmall piece of brass dec with three holes, at dec.

The manner of putting it upon the globe is this: first put the crescent a b, on the string; and the piece of brass, by passing the string through the two holes d, e, the string being as yet left free. The two ends of the string being loose, pass the end F round the north pole of the globe, in a groove made for that purpose, and tie it into a loose loop like F g, then put the other end of the string G c round the south pole, and tie it fast to the hole at c: then by pulling the piece d e c upwards, the string may be

be tightned on any part of the globe, and pushing it downwards will flacken it, that it may be removed to any other place, and then tightned again.

#### PROBLEM XIV.

To represent the apparent diurnal motion of the fun, moon, and ftars, on the celestial globe.

197. Find the fun's place in the ecliptic, by problem 1. art. 98. and to that point on the ecliptic line which is drawn upon the globe, fet the center of the artificial fun. Alfo,

Find the moon's place by problem xiii. art. 194. and fet the center of the artificial moon upon it.

Rectify the globe to the latitude, fun's place, and zenith, by problem xii. art. 189, 190, and 192.

The globe being turned round its axis from east to west, will represent the apparent motion of the sun, moon, and stars, for that day.

198. When the center of the artificial fun is in the plane of the horizon on the I eaftern

eastern fide, the horary index shews upon the equator the time of fun rifing.

199. All those stars which are then in the plane of the horizon on the eastern fide, are at the same instant of time rising with the fun, and those on the western fide of the horizon, are then setting.

Their distance from the true east or west points of the horizon, is called the sun or star's amplitude.

200. And when the center of the artificial moon comes to the horizon on the eaftern fide, the horary index will point to the hour and minute of her rifing.

And those stars on the eastern edge of the horizon are then rising with her, whils at the same time all the stars, cut by the western edge, are setting.

201. That degree and minute of the equator which is cut by the plane of the horizon, at the fame time that the center of the artificial fun, moon, or any flar, is alfo cut by the faid plane, is the very point of the equator, which rifes with either of them, and is called the fun, moon, or flar's oblique 'afcenfion.

202. As

<sup>1</sup>202. As the fun afcends in the heavens till it culminates, or comes under the graduated fide of the ftrong brafs meridian, the horary index will fucceffively point to the hours before noon; but when it is under it, the horary index points at XII o'clock, and that degree and minute on the equator, which is then cut by the brafs meridian, is called the fun's right afcenfion, that is, its diftance from the first point of Aries, reckoned in degrees, minutes, &c. upon the equator.

203. At the fame time, that degree of the brafs meridian, which is directly over the artificial fun, is his declination, art. 133. for that day.

The fame is to be obferved of the moon or any ftar, as they afcend in the heavens, till they culminate or come under the meridian, the horary index conftantly pointing to the hour of the day or night; their right afcention and declination are also thewn in the fame manner as that of the fun.

204. Whilft the fun descends from the meridian westward, the horary index succeffively shews the hours after noon.

I 2

And

And when the center of the artificial fun is in the plane of the horizon on the western fide, the horary index shews the time of sun fetting; and that point of the equator which is then cut by the plane of the horizon, is the point which sets with the sun, and is called his oblique descension.

205. The number of degrees on the equator contained between the points of his oblique ascension, and right ascension, or between the points of his right ascension and oblique descension, is called his ascenfional difference.

Observe the same with respect to the moon or any star: as they descend from the meridian westward, the horary index will successively shew the time of their arrival at any given point, their setting, oblique descension and ascensional difference, in the fame manner as before described in relation to the fun.

The rifing, culminating, fetting, &c. of any planet may be obtained, if the place of the planet, its longitude and latitude being taken from an ephemeris, be afcertained; and an artificial planet fet thereto, in the manner in which we have directed the artificial

ficial moon to be placed upon the globe, art. 196. or this last may occationally represent a planet.

Thus on the 18th day of June, A. D. 1769 new ftile, being the first year after biffextile, the fun's place will be 11, 27 deg. 22 min. the moon's place 2, 18 deg. 0 min. her latitude north 0 deg. 30 min. The full moon about  $\frac{1}{2}$  of an hour past VIII. 0'clock in the morning; to which places, if the artificial fun and moon be fet, a beginner may readily exercise himself in finding the proper answers agreeable to these data, by the directions in this problem.

# Parallels of altitude.

206. The globe remaining rectified as in the laft problem, the uppermoft point reprefents a point in the heavens directly over our heads, which is called the zenith: and as the brafs quadrant is moveable about its upper end as a center, when that center is fixed to the latitude of the place upon the ftrong brafs meridian, it will be in the zenith, and the beginning of its graduations will coincide with the plane of the broad paper I 3

circle, which in these cases represents the horizon of the place.

If the quadrant be moved about the globe, its first division will describe the horizon. And,

At the fame time, all its intermediate divisions will describe circles parallel to the horizon; the point marked 10 describes a parallel of 10 degrees, the point marked 20 a parallel of 20 degrees, and so of any other point.

207. These circles parallel to the horizon are called parallels of altitude, because they shew the elevation of the sun, moon, stars, or planets, above the plane of the horizon:

And the divisions on the quadrant itself in each case represent the distance of every secondary to the horizon.

# PROBLEM XV.

To find the fun's altitude at any given time of the day.

208. Set the center of the artificial fun to his place in the ecliptic upon the globe; and rectify it to the latitude and zenith, by problem

problem xii. art. 189, &c. bring the center of the artificial fun under the ftrong brafs meridian, and fet the hour index to that XII which is most elevated; turn the globe to the given hour, and move the graduated edge of the quadrant to the center of the artificial fun; and that degree on the quadrant which is cut by the fun's center, is the fun's height at that time,

The artificial fun being brought under the strong brass meridian, and the quadrant laid upon its center, will shew its meridian, or greatest altitude, for that day.

If the fun be in the equator, his greatest or meridian altitude is equal to the elevation of the equator, which is always equal to the co-latitude of the place.

### Azimuth or vertical circles.

209. An azimuth circle in aftronomy, is the very fame as a circle of position in geography; they being secondaries to the horizon, or great circles passing through the zenith of any place, and crossing the horizon at right angles: either in the heavens, called azimuths; or on the earth, circles of position.

I 4

Any

Any azimuth circle may be reprefented by the quadrant of altitude, when the center upon which it turns, is fcrewed to that point of the ftrong brafs meridian, which anfwers to the latitude of the place, and the place brought into the zenith.

Suppose at London, if you bring the divided edge of the quadrant to 10 degrees on the inner edge of the broad paper circle, it will represent an azimuth circle of, 10 degrees; if you set it to 20, it will represent an azimuth circle of 20 degrees; and so of any other.

If the quadrant of altitude be fet to o degree, that is either upon the eaft or weft points of the broad paper circle, it will then represent that secondary to the horizon, or azimuthal circle, which is called the prime vertical.

#### PROBLEM XVI.

# To find the azimuth of the fun, or any star.

210. Reclify the globe to the latitude and fun's place, art. 189, 190. then turn it to the given hour, and bring the divided edge

edge of the quadrant of altitude to the fun's place in the ecliptic, or to the center of any ftar, and it will cross the horizon at the azimuth required.

The diftance of that point of the horizon, in which the fun appears to rife or fet, counted from the prime vertical, art. 209. or east and west points of the horizon, is called the fun's amplitude.

#### COROLLARY.

# To find the angle of polition of places.

211. The angle of polition is that formed between the meridian of one of the places, and a great circle paffing through the other place.

Rectify the globe to the latitude and zenith of one of the places, art. 189, 192. bring that place to the ftrong brass meridian, set the graduated edge of the quadrant to the other place, and the number of degrees contained between it and the strong brass meridian, is the measure of the angle fought. Thus,

The

The angle of position between the meridian of Cape Clear in Ireland, and St. Augustine in Florida, is about 82 degrees north westerly; but the angle of position between St. Augustine and Cape Clear, is only about 46 degrees north easterly.

Hence it is plain that the line of position, or azimuth, is not the same from either place to the other, as the romb-lines are,

#### COROLLARY.

# To find the bearing of one place from another.

212. The bearing of one fea-port from another is determined by a kind of fpiral called a romb-line, paffing from one to the other, fo as to make equal angles with all the meridians it paffeth by; therefore if both places are fituated on the fame parallel of latitude, their bearing is either eaft or weft from each other; if they are upon the fame meridian, they bear north and fouth from one another; if they lie upon a rombline, their bearing is the fame with it; if they do not, obferve to which romb-line the two

table 1

two places are nearest parallel, and that will shew the bearing fought.

Thus the bearing of the Lizard Point from the island of Bermudas is nearly ENE; and that of Bermudas from the Lizard is WSW, both nearly upon the fame romb, but in contrary directions.

# A parallel fphere

213. Is that polition of the globe, in which the poles are in the zenith and nadir, its axis at right angles to the equator and horizon, which coincide; and confequently those circles which are parallel to the equator, are alfo parallel to the horizon.

The inhabitants of this fphere, if any there be, must live upon the two terrestrial poles, and will have but one day and one night throughout the year; and the moon, during half her monthly course, will never rise, and during the other half will never fet; all the fixed stars, visible to those people, will describe circles every day parallel to their horizon.

A right

# A right fphere

214. Is that in which the inhabitants fee both poles in their horizon, the equator passing through their zenith and nadir, and all the circles parallel to the equinoctial perpendicular to their horizon.

These people live upon the terrestrial equator, consequently all the heavenly bodies will always rife and set perpendicularly to them; and their days and nights will be of an equal length throughout the year.

# An oblique sphere

215. Hath one of the poles of the globe above, the other under the horizon; the equator in all the cafes of this fphere is half above, and half below the horizon, and all its parallel circles cut the horizon obliquely.

That arch of any parallel of declination in the celeftial, or of latitude in the terreftrial fphere that is above the horizon, is called the diurnal arch. And

The remaining part of it, which is below the horizon, is called the nocturnal arch.

12 22

Thefe

These arches, with respect to the sun's apparent motion, determine the different length of days and nights.

The inhabitants of this fphere are those who live on all parts of the earth, except those at the poles and upon the equator.

# Of the twilight.

That light which we have from the fun before it rifes, and after it fets, is called the twilight.

216. The morning-twilight, or day-break, begins when the fun comes within 18 degrees of the horizon, and continues till funrifing.

The evening twilight begins at the time of the fun-fetting, and continues till it is 18 degrees below the horizon.

For this purpose on our new-globes, a wire circle is fixed eighteen degrees below the surface of the broad paper circle; so that

All those places which are above the wire circle will have the twilight, but it will be dark to all places below it.

At the time of winter folftice, when the whole space within the northern polar circle

is

is out of the fun's light, the greater part of it enjoys the benefit of twilight y, there being only about  $5\frac{1}{2}$  degrees round the pole that will be totally dark.

We have here only confidered the twilight reflected to us from the earth's atmofphere by the fun himself; besides which the body of the fun is always encompassed with a sphere of light, which being of a larger circumference than the fun, must rife before him, and fet after him; which confequently lengthens the twilight by illuminating our air, when the fun is depressed too low to reach it with his own light: this feems to be the caufe, why the fun is preceded by a luminous legment of a circle in the east before his rising, different from that light reflected by the atmosphere from the body of the fun; the like to which may be observed in the west after sun-set.

# To reprefent the earth's enlightened difc by the terrettrial globe.

217. We have already shewn how the earth's diurnal motion is represented by the motion of the terrestrial globe about its axis from

from west to east; and that the horary index will point upon the equator the 24 hours of one diurnal rotation, or any part of that time.

The broad paper circle, under this confideration, will be now employed to reprefent a plane fuppofed to pass through the center of the earth, perpendicular to a central folar ray: or in other words, perpendicular to a line supposed to be drawn from the center of the fun to that of the earth at all times of the year.

In which cafe, the broad paper circle divides that half of the earth's furface, which is illuminated by the fun's rays, from the other hemifphere which is not enlightened.

218. That the globe may appear to be 'fo enlightened, conceive a fun painted on the ceiling of the room in which you are, 'directly over the terreftrial globe, and of the fame diameter; from whence imagine an infinite number of parallel rays falling perpendicularly downwards upon the upper furface of the globe, which here reprefents the illuminated hemisphere of the earth's enlightened difc.

Carlos .

Whence

Whence it is plain, that the central folar ray is the only one which paffes through the centers of the fun and earth, as well as the only ray that can poffibly be perpendicular to the earth's furface; all other folar parallel rays will fall more and more oblique, as they are farther from the central ray, till their arrival at the edge of the enlightened difc, here reprefented by the inner edge of the broad paper circle, where they will become parallel to the horizons of all places then under the faid edge of the difc.

In one diurnal revolution of the earth, the central folar ray defcribes the parallel of the fun's declination; or rather that parallel, to the inhabitants of which the fun that day will pass directly vertical, or over their heads.

From this application of the terrestrial globe, we see the natural cause of the different altitudes of the sun at different times of the day, and at different seasons of the year; which arise from the earth's daily rotative and progressive motion, &cc.

When we view the globe in this polition, we at once fee the fituation of all places in the

the illuminated hemisphere, whose inhabitants enjoy the light of the day, while at the same time all those places below the broad paper circle, are deprived of the sun's light, and have only twilight so far as the wire circle, and all below that, have total darkness, when the moon does not shine on them.

And by observing the angles made by the meridians, drawn on the globe, cutting any parallel of latitude at the edge of the broad paper circle, with the strong brass meridian, we see the semi-diurnal arches continually decrease from the elevated pole, till they come to the opposite part of the earth's enlightened difc.

### PROBLEM XVII.

To rectify the terreftrial globe, that the enlightened half of the earth's furface may be all above the broad paper circle for any time of the year; the fun being fuppofed in the zenith.

219. On the backfide of the ftrong brass meridian, and on each fide of the north pole,

arc
are graduated, in two concentric spaces, the months and days of the year.

Bring the day of the month to coincide with the broad paper circle, and the terreftrial globe is rectified.

When the globe is thus rectified, that degree and minute upon the graduated fide of the brass meridian, which is then cut by the plane of the broad paper circle, is the distance of the stude of extuberancy upon the earth's disc, reckoned from the pole, and is equal to the fun's declination for that day; and is therefore also equal to the latitude, counted from the equator, of all those places to which the fun is vertical; and this point on the brass meridian reprefents the central folar ray describing the parallel of the day.

If now the globe be turned from west to east, all those places which arrive at the western edge of the broad paper circle, are passing out of the twilight into the sun's light; and the sun then appears rising to all the inhabitants.

At the fame time, if you look upon the eastern edge of the broad paper circle, it will cut all those places which are then passing

paffing from the fun's light into the twilight; whofe inhabitants will fee the fun fetting, and enjoy the twilight, until they arrive at the wire circle, which is placed 18 degrees below the illuminated difc, at which time they enter into total darknefs.

The graduated fide of the ftrong brafs meridian shews, at the fame time, all those places which have mid-day or noon.

- If the horary index be fet to XII, when any particular place is brought under the ftrong brafs meridian, it will fhew, as you turn the globe from weft to caft, the precife time of fun-rifing, fetting, &cc. at that place.

The horary index will also shew how long a place is moving from the west to the east fide of the illuminated disc, here represented by the broad paper circle, and thence the length of the day and night; it will also point out the length of the twilight, by shewing the time in which the place is passing from the twilight circle to the edge of the disc on the western fide, or from the edge of the disc to that circle on the eastern fide; and thereby determining the length of its whole artificial day.

K 2

We

We shall proceed to exemplify these particulars at the times of equinox and folfice.

#### PROBLEM XVIII.

#### The time of equinox.

220. The fun has no declination at the times of equinox, confequently there must be no elevation of the poles.

Bring the day of the month on the backfide of the firong brafs circle, in which the fun enters the first point of Aries or Libra, into the plane of the broad paper circle, and then the two poles of the globe will be in that plane also; and all those circles which are parallel to the equator will cut the plane of that broad circle at right angles, and the globe will then represent a right sphere.

If you now turn the globe from weft to eaft, it will plainly appear, that all places upon its furface are twelve hours above the broad paper circle, and as many below it; which fhews, that the nights are equal to the days to all the inhabitants of the earth; that is, they are illuminated by the fun's rays twelve hours: whence thefe are called the equinoctial feafons, two of which occur in every

every year; the first is the autumnal, the fecond the vernal, equinox.

At these times the sun appears to rise and set at the same instant to all places in the same meridian.

But their twilight is longer as their fituation is nearer to either pole; in fo much that within 18 degrees of the poles, their twilight is 12 hours, confequently there is no dark night in those places at the times of equinox: when at the same time those places under the equator have only one hour and 12 minutes twilight; so that their artificial day is about 14 h. 24 min. at these two feasons of the year.

Thus, if London and Mundford on the Gold Coaft, be brought to the ftrong brafs meridian, the graduated fide of which is in this cafe the horary index; (tho' in other cafes the hour index is to be fet to that XII which is most elevated;) if then they be brought to the west fide of the broad paper circle, the index will point to VI o'clock for fun-rifing, and to VI for fun-fetting, when these places are brought to the eastern fide.

K 3

Alfo,

Alfo, if London be turned from the weft towards the eaft, and the hour index be fet to XII as before, if you turn it till the ifland of Jamaica comes to the meridian, it will fhew, on the equator, the hour after noon at London, when it is noon at Jamaica; or that London paffes under the meridian about 5 h. 4 min. before Jamaica arrives at it.

#### PROBLEM XIX.

#### The fummer solftice.

221. Rectify the globe to the extremity of the divisions for the month of June, or to  $23\frac{1}{2}$  degrees north declination; then that part of the earth's furface, which is within the northern polar circle, will be all illuminated by the fun, and the inhabitants thereof will have continual day.

But all that fpace which is contained within the fouthern polar circle, will be at the fame time in the fhade, and have continual night.

222. In this position of the globe, we fee how the diurnal arches of the parallels of latitude decrease, as they are more and more distant from the elevated pole.

223. If

223. If any place be brought under the ftrong brass meridian, and the horary indexbe fet to that XII which is most elevated, and if that place be brought to the western fide of the broad paper circle, the hour index will shew the time of fun-rising; and when moved to the eastern edge, the index points to the time of fun-fetting; the length of the day is obtained by the time shewn by the horary index, while the globe is turned from the west to the east side of the illuminated difc.

Thus it will be found that at London the fun rifes about 15 minutes before IV in the morning, and fets about 15 minutes after VIII at night.

At the following places it will be nearly at the times expressed.

the state of the s	Rit	G Setting.			Length of Day		Twi-	
	h.	m.	h.	m.	h.	m.	h.	<b>m</b> .
Cape Horn	8	44	3	16	6	32	2	35

alalant malate	K	4		25-	13.00		-	We

We also fee, that at the time when the fun rifes at London, it rifes at the island of Sicily in the Mediterranean, and at the island of Madagafcar.

And that at the time when the fun fets at London, it is fetting at the island of Madeira, and at Cape Horn.

And when it is fun-fetting at the island of Borneo in the East Indies, the fun is rifing at Florida in America.

#### PROBLEM XX.

## Winter folftice.

224. Rectify the globe to the extremity of the divisions for the month of December, or to  $23\frac{1}{2}$  degrees fouth declination.

At this feafon it will be apparent, that the whole fpace within the fouthern polar circle is in the fun's light, and enjoys continual day; whilft that of the northern polar circle is in the fhade, and has continual night.

Then if the globe be turned as before, the horary index will shew, that at the feveral places before mentioned, their days will be respectively equal to what their nights

nights were at the time of the fummer folftice.

It will appear to be fun-fetting at the time it was then fun-rifing; and on the contrary, fun-rifing at the time it then appeared to fet.

#### The terrestrial horizon,

225. As has been defcribed art. 117. is a fmall brais circle with one diameter that paffes through its center; its circumference is divided into eight parts, which are marked with the initial letters of the mariner's compaís, the four cardinal points of the horizon being diffinguished from the reft; this may be flipped from pole to pole on the moveable meridian, and by this means be fet to any place upon the globe.

When the center of it is fet to any particular place, the fituation of any other places is feen with respect to that place; that is, whether they be east, west, north, or south; thus it represents the sensible horizon.

It will also shew, why the sun appears at different altitudes and azimuths, although he is supposed to be always in the same place.

PROBLEM

#### PROBLEM XXI.

## The fun's altitude, as observed with a terrestrial or visible horizon.

226. The altitude of the fun is greater or lefs, according as one of the parallel right lines or rays, coming from the fun to us, is farther from, or nearer to, our horizon.

Apply the terrestrial horizon to London, the fun being supposed in the zenith, or on the ceiling directly over the globe.

If then from London a line pass vertically upwards, the fun will be feen from London in that line.

At fun-rifing, when London is brought to the weft edge of the broad paper circle, the fuppofed line will be parallel to the terreftrial horizon, and from London will be then feen in the horizon.

As the globe is gradually turned from the weft towards the eaft, the horizon will recede from the line which paffes perpendicularly upwards; for the line in which the fun was then feen, feems to glide farther and farther from the terrestrial horizon; that is, the fun's altitude increases as gradually

dually as that line declines from the terreftrial horizon.

When the horizon, and the line which goes from London vertically upwards, are arrived at the ftrong brass meridian, the sun is then at his greatest or meridian altitude for that day; then the line and horizon are at the largest angle they can make that day with each other.

After which, the motion of the globe being continued, this angle between the terreftrial horizon and the line, which goes from London vertically upwards, continually decreases, until London arrives at the eastern edge of the broad paper circle; its. horizon then becomes vertical again, and parallel to the line which goes vertically upwards, and will then appear in the horizon, and be seen to set.

#### PROBLEM XXII.

# The fun's meridian altitude at three different feafons.

227. Rectify the globe to the time of winter folftice, art. 224. and place the center of the visible horizon on London.

When

When London is at the graduated edge of the ftrong brass meridian, the line which goes vertically upwards, makes an angle of about 15 degrees; this is the fun's meridian altitude at that season to the inhabitants of London.

228. If the globe be rectified to the time of equinox, art. 220. the horizon will be farther feparated from the line which goes vertically upwards, and makes a greater angle therewith, it being about  $38\frac{1}{2}$  degrees; this is the fun's meridian altitude at the time of equinox at London.

229. Again rectify the globe to the fummer folftice, art. 221. and you will find the visible horizon recede farther from the line which goes from London vertically upwards; and the angle it then makes with the horizon, is about 62 degrees, which shews the fun's meridian altitude at the time of the fummer folftice.

Hence flows the following arithmetical

PROBLEM

## PROBLEM XXIII. To find the fun's meridian altitude univerfally.

230. Add the fun's declination to the elevation of the equator, if the latitude of the place and declination of the fun are both on the fame fide.

If on contrary fides, fubtract the declination from the elevation of the equator, and you obtain the fun's meridian altitude.

Thus, the elevation of the equator at 38 London Sun's declination May 20th 20	1 28 8
Their fum is the fun's meridian alti- tude for that day at London 358	36
Again, to the elevation of the equator at London, Add the fun's greatest declination at the time of the fummer folftice, 323	28 29
Their fum is the fun's greatest meri- $361$ dian altitude at London,	57
Whence also flows another method,	To

To find the fun's greatest and least altitude universally.

231. Add the fun's declination to, and fubtract it from the elevation of the equator, their fum and difference will be the fun's meridian altitudes, when he hath the fame declination either north or fouth.

Thus, to and from the elevation of 38 28 the equator, Add and fubtract the fun's decli-320 8 Their for inches for a maridian eltip 2

Their fum is the fun's meridian alti-358 36 tude in fummer,

Their difference his meridian altitude 318 20 in winter,

having the fame declination one north, the other fouth.

#### PROBLEM XXIV.

The fun's azimuth compared with the visible horizon.

232. Imagine the fun, as we have done before, to be painted on the ceiling directly over

over the globe, art. 218. and a line going vertically upwards towards the fun from any place on the furface of the globe :

If to that place you apply the visible horizon, that point of it which a vertical line is nearest to at any time, shews the fun's azimuth at that time : and we must also obferve, that that point of the terrestrial or visible horizon, to which a vertical line is nearest, is always the most elevated point.

233. Rectify the globe to the position of a right sphere, art. 214. and apply the visible horizon to London. When London is at the western edge of the broad paper circle, which situation represents the time when the sun appears to rise, the eastern point of the visible horizon being then most elevated, shews that the sun at his rising is due east.

Turn the globe till London comes to the eastern fide of the paper circle, then the western point of the visible horizon will be most elevated, and shew that the fun sets due west.

If the globe be rectified into the polition of an oblique fphere, art. 215, and London be brought to the eastern or western fide of the

the broad paper circle, the vertical line will depart more or lefs from the east and west points: in which cases the fun is faid to have more or lefs amplitude either north or fouth, as this departure tends to either of those two cardinal points.

As the globe is turned to any particular time of the day, we shall have the fun's azimuth upon that point of the visible horizon which is most elevated; and this will be the point wherein a line going towards the fun is nearess to a vertical line; thus, if a line going towards the fun, be nearess the fouth-east point, the fun is then faid to have 45 degrees azimuth eastward, that point being 45 degrees from the meridian.

234. In all politions of the globe in north latitude, when London is brought to the ftrong brass meridian, the most elevated point of the visible horizon will always be the south point of it, which shews that the fun; at all seasons of the year, will appear to the south of the terrestrial horrizon in all places included in the northern temperate zone; but to the north of it at those places within the southern temperate zone.

235. The

235. The ancient diffinction of the different places on the earth, according to the diverfity of the shadows of upright bodies at noon.

### PROBLEM XXV.

- tot sill di amosi

MR3302

The afcii, or those who on a certain day project no shade at noon.

236. Rectify the globe by problem xix. art. 221. to the time of the fummer folftice, and apply the terrestrial horizon to any place situated on the tropic of Cancer, as Canton in China, and observe the fun's meridian altitude with it, by bringing its center under the strong brass meridian, art. 226. it will then appear, that a line going vertically upwards, will be perpendicular to it, consequently the sun will be at that time directly over the heads of the inhabitants of Canton, and project no shadow; therefore they are ascii, their noon-shadow being directly under them.

L

At

At all other times of the day, their fhadow is projected, in the morning directly westward, and in the evening directly eastward.

The fame thing will happen to all the inhabitants, who live between the tropic of Cancer and that of Capricorn, if the terreftrial horizon be gradually removed from parallel to parallel within thefe limits, and the globe rectified according to the day of the month as before directed; by bringing the fentible horizon to the ftrong brafs meridian, to obferve the fun's meridian altitude, we fhall find him appear to be 90 degrees high, or vertical, at noon, to every place between the tropics; all the inhabitants being afcii twice a year, except thofe on the tropics themfelves, who are afcii only once a year.

#### PROBLEM

#### PROBLEM XXVI.

The inhabitants of all places between the tropics of Cancer and Capricorn, are not only afcii, but amphifcii, whofe noon-schadows are projected sometimes towards the north, at other times towards the fouth.

237. Place the fensible horizon on the equator, and rectify the globe to the time of the equinox, art. 220. at which time the equatorial inhabitants are afcii at noon, having the fun full east of them all the morning, and full west all the afternoon.

The eastern point of the sensible horizon will be always uppermost, or most elevated, as the globe is moved from west to east, till it comes to the strong brass meridian; and after it has passed this, the western point will be most elevated.

The fenfible horizon remaining on the equator, rectify the globe to the time of the fummer folftice, art. 221. and you will L 2 find

find the north point at noon will be most elevated; which plainly shews, that the inhabitants of the equator will see the sun full north at that season, and that their shade will be projected southwards.

238. If the globe be rectified to the winter folftice, art. 224. the fouth point will be most elevated, and the inhabitants will fee the fun on their fouth fide, which will project their shadows northwards.

239. Heterofcii, are those who live between the tropics and polar circles, whose noon-shadows are projected one way only.

Those in north latitude have their noonshadows projected northwards; the sun at that time being always in the south.

And those in south latitude have their noon-tide shadows projected southwards; the meridian sun always appearing to them in the north.

240. Periscii are those who live within the polar circles, the sun going continually round them, their shadow must necessarily go round them also.

If the fenfible or terrestrial horizon be applied to any of these places, and the globe rectified according to the preceding directions,

tions, it will fhew, that the fun appears to be more elevated at one time of the day than at another; and alfo, which way at all times the noon and other fhadows are caft.

241. Antœci are two opposite nations, lying in or near the fame meridian, one of them in north, the other in fouth latitude; they have both the fame longitude, and equal latitude, but on opposite fides of the equator: they have opposite feasons of the year, but the fame hours of the day.

242. Periœci are two nations fituated on opposite fides of the globe, in the fame parallel of latitude, having the fame feasons of the year, and opposite hours of the day.

Therefore their longitude must differ . 180 degrees.

243. Antipodes are two nations diametrically opposite, which have opposite feasons as well as opposite hours.

A ftraight line passing from one to the other must consequently pass through the center, and therefore become a diameter of the globe.

Their longitude and latitude are both oppofite.

L 3

Thefe

These are exemplified by rectifying the globe into the position of a right sphere, art. 220. and bringing the nations under confideration to the edge of the broad paper circle. Thus,

The inhabitants of the eastern parts of Chili are Antœci to those of New England; whose Periœci live in the northern parts of China, who are also antipodes to the inhabitants of Chili.

We shall now proceed to exemplify the former precepts in a few particular problems,

#### PROBLEM XXVII.

To find all those places on the globe, over whose zenith the sun will pass on any given day.

244. Rectify the terrestrial globe, art. 219. by bringing the given day of the month, on the backfide of the strong brass meridian, to coincide with the plane of the broad paper circle, and observe the elevation of the pole on the other side; and that degree counted from the equator on the strong brass meridian, towards the elevated pole,

pole, is the point over which the fun is vertical. Now turning the globe, all those places which pass under this point, have the fun directly vertical on the given day.

Thus bring the 1 1th day of May, into the plane of the broad paper circle, and the faid plane will cut 18 degrees for the elevation of the pole, which is equal to the fun's declination for that day; which counted on the ftrong brass meridian towards the elevated pole, is the point over which the fun will be vertical. Now turning the globe round, we shall find that Amalagan, one of the Ladrone islands, the northern part of Manilla, the middle of Siam, a great part of Africa, and St. Anthony one of the Cape Verd Isles, the fouthern fide of the islands Porto-Rico and Domingo, and the northern part of the island of Jamaica, &c. have all of them the fun in their zenith on the 11th of May.

Hence when the fun's declination is equal to the latitude of any place in the torrid zone, the fun will be vertical to those inhabitants that day.

Hence alio we derive the following

an will can the

L 4

PRO-

#### PROBLEM XXVIII.

To find the fun's declination, and thence the parallel of latitude corresponding therewith, upon the terrestrial globe.

245. Find the fun's place upon the broad paper circle for any given day, art. 98. and feek that place in the ecliptic line upon the globe; this will fhew the parallel of the fun's declination among the dotted lines, which is alfo the corresponding parallel of latitude; therefore all those places through which this parallel paffes, have the fun in their zenith at noon on the given day.

#### PROBLEM XXIX.

To find those two days on which the fun will be vertical to any place between the tropics.

246. That parallel of declination which paffes through the given place, will cut the ecliptic line upon the globe in two points, which

which denote the fun's place, against which, on the broad paper circle, are the days and months required.

#### PROBLEM XXX.

The day and hour at any place being given, to find where the fun is vertical at that time.

247. Let the given place be London, and time the .1 1th day of May at 4 minutes paft V in the afternoon.

Rectify the globe to the day of the month, art. 219. and you have the fun's declination 18 degrees north; bring London to the meridian, and fet the horary index to XII, turn the globe till the index points to the given hour on the equator, 4 minutes paft V, then Port-Royal in Jamaica will be under the 18th degree of the ftrong brafs meridian, which is the place where the fun is vertical at that inftant.

. PROBLEM

## PROBLEM XXXI.

which denote th

The time of the day at any one place being given, to find all thofe places in which the fun is then rifing, fetting on the meridian, and where he is vertical; likewife thofe places, in which it is midnight, twilight, and darknight, at the fame inftant; as well as thofe places in which the twilight is beginning and ending; and alfo to find the fun's altitude at any hour in the illuminated, and his deprefion in the obfcure, hemifphere,

248. Rectify the globe to the day of the month, art. 219. on the backfide of the strong brass meridian, and the sun's declination for that day, which is equal to the elevation of the pole, is given upon the graduated side of the brass meridian, by its coincidence with the plane of the broad paper

paper circle; bring the given place to the ftrong brafs meridian, and fet the horary index to XII, upon the equator, turn the globe from weft to east, until the horary index points to the given time. Then

All those places, which lie in the plane of the western side of the broad paper circle, fee the fun rising, and at the same time those on the eastern side of it see him setting.

It is then noon to all the inhabitants of those places under the upper half of the graduated fide of the strong brass meridian, whilst at the same time those under the lower half have mid-night.

All those places, which are then between the upper furface of the broad paper circle, and the wire circle under it, are in the twilight; which begins to all those places on the western fide that are immediately under the wire circle, to which it is the dawning of the day; its end is at all those places in the plane of the paper circle, on which the fun has just begun to rife.

The contrary happens on the eaftern fide; the twilight is just beginning to those places in which the fun is setting, and its end is at the place just under the wire circle.

And

And all those places which are under the twilight wire circle have dark night, unless the moon is favourable to them.

All places in the illuminated hemisphere have the fun's altitude equal to their distance from the edge of the enlightened disc, which is known by fixing the quadrant of altitude to the zenith, and laying its graduated edge over any particular place.

The fun's depression is obtained in the fame manner by fixing the center of the quadrant at the nadir.

#### PROBLEM XXXII.

To find the time of the fun's rifing and fetting, the length of day and night, on any day in the year, in any place, whofe latitude lies between the polar circles, and alfo the length of the fhortest day and night in any of those latitudes, and in what climate they are.

249. Rectify the celestial globe to the latitude of the given place, art. 189. bring the

the artificial fun to his place in the ecliptic for the given day of the month; and then bring its center under the firong brass meridian, and set the horary index to that XII which is most elevated.

Then bring the center of the artificial fun to the eaftern part of the broad paper circle, which in this cafe reprefents the horizon, and the horary index fhews the time of the fun-rifing; turn the artificial fun to the weftern fide, and the horary index will fhew the time of the fun-fetting.

Double the time of fun-rifing is the length of the night, and the double of that of funfetting is the length of the day.

Thus on the 5th day of June, the fun rifes at 3 h. 40 min. and fets at 8 h. 20 m. by doubling each number it will appear, that the length of this day is 16 h. 40 m. and that of the night 7 h. 20 m.

The longest day at all places in north latitude, is when the sun is in the first point of Cancer. And,

The longest day to those in south latitude, is when the sun is in the first point of Capricorn.

Wherefore

Wherefore the globe being rectified as above, and the artificial fun placed to the first point of Cancer, and brought to the eastern edge of the broad paper circle, and the horary index being fet to that XII which is most elevated, on turning the globe from east to west, until the artificial fun coincides with the western edge, the number of hours counted, which are passed over by the horary index, is the length of the longest day; their complement to twenty-four hours gives the length of the shortest night.

250. If twelve hours be fubtracted from the length of the longeft day, and the remaining hours doubled, you obtain the climate mentioned by ancient historians: and if you take half the climate, and add thereto twelve hours, you obtain the length of the longeft day in that climate; this holds good for every climate between the polar circles.

A climate is a fpace upon the furface of the earth, contained between two parallels of latitude, fo far diftant from each other, that the longest day in one, differs half an hour from the longest day in the other parallel.

The

The climates are reckoned from the equator to the polar circle, where the longeft day is twenty-four hours; from the polar circle towards the pole the climates are faid to encrease by a whole natural day, till they came to a parallel under which the longest day is fifteen natural days, or half a month, from this the climates are reckoned by half months, or whole months, in the length of the artificial day, till they come to the pole itself, under which the day is fix months long.

#### PROBLEM XXXIII.

To find all those places within the polar circles, on which the fun begins to fhine, the time he fhines conftantly, when he begins to disappear, the length of his abfence, as well as the first and last day of his appearance to those inhabitants; the day of the month, or latitude of the place, being given.

251. Bring the given day of the month on the backfide of the strong brass meridian,

to the plane of the broad paper circle, the fun is just then beginning to shine on all those places which are in that parallel, just touched by the edge of the broad paper circle; and will for several days seem to skim all around, and but a little above the horizon, just as it appears to us at its setting; but with this observable difference, that whereas our setting fun appears in one part of the horizon only, by them it is seen in every part thereof; from west to south, thence east to north, and so to the west again.

Or if the latitude was given, elevate the globe to that latitude, and on the backfide of the ftrong brass meridian you obtain the day of the month, then all the other requifites are answered as above.

As the two concentric spaces which contain the days of the month on the backfide of the strong brass meridian, are graduated to shew the opposite days of the year, at 180 degrees distance; when the given day is brought to coincide with the broad paper circle, it shews when the fun begins to shine on that parallel, which is the first day of its appearance above the horizon of that parallel;

lel: and the plane of the faid broad paper circle cuts the day of the month on the oppolite concentric space, when the fun begins to difappear to those inhabitants; thus the length of the longest day is obtained, by reckoning the number of days between the two opposite days found as above; and their difference from 365 days gives the length of their longest night.

## PROBLEM XXXIV.

## To find the length of any day in the year, in any latitude.

252. Elevate the celeftial globe to the latitude, and fet the center of the artificial fun to his place upon the ecliptic line on the globe for the given day, and bring its center to the ftrong brass meridian, placing the horary index to that XII which is most elevated; then turn the globe till the artificial fun cuts the eastern edge of the horizon, and the horary index will shew the time of fun-rifing; turn it to the western fide, and you obtain the hour of fun-fetting.

ROBLEM

The

The length of the day and night will be obtained, by doubling the time of fun-rifing and fetting, as before.

# PROBLEM XXXV.

To find the length of the longest and shortest days in any latitude.

253. Elevate the globe according to the latitude, art. 189. and place the center of the artificial fun for the longest day upon the first point of Cancer, but for the flortest day on the first point of Capricorn, then proceed as in the last problem:

But if the place hath fouth latitude, the fun is in the first point of Capricorn on their longest day, and in the first point of Cancer on their shortest day.

Note, This problem is only to be used in such latitudes as lie between the northern and southern polar circles.

fon outs the effect edge of the horizon, and the hority index will fiew the time of funerifing , turn it to it weltern file, and

vou bleak the hour of an enlar

#### PROBLEM

## PROBLEM XXXVI.

To find the latitude of a place, in which its longeft day may be of any given length between twelve and twenty-four hours.

254. Set the artificial fun to the first point of Cancer; bring its center to the strong brass meridian, and set the horary index to XII; turn the globe till it points to half the number of the given hours and minutes; then elevate or depress the pole, till the artificial sun coincides with the horizon, and that elevation of the pole is the latitude required.

### PROBLEM XXXVII.

## To find the diftance between any two places.

255. Lay the graduated edge of the quadrant of altitude over both places, and the number of degrees between them is their diftance, which is reduced to geographical miles, by reckoning 60 to a degree, or  $M_2$ . to
to English miles by reckoning  $69\frac{1}{2}$  to one degree.

If both places lie under the fame meridian, their difference of latitude is the diftance required.

If they are in the fame parallel of latitude, their difference of longitude is the diftance fought.

# PROBLEM XXXVIII.

To find all those places which are at the same distance from a given place.

256. Rectify the globe by problem XII, art. 189. and bring the given place to the ftrong brass meridian, over which fcrew the center upon which the quadrant of altitude turns; now move the quadrant round, and all those places, that are cut by any one point on the quadrant, are equally distant from the given place.

PROBLEM

# PROBLEM XXXIX.

To fhew at one view upon the terreftrial globe for any given place, the fun's meridian altitude, his amplitude, or point of the compass, on which he rifes and sets every day in the year.

257. Rectify the globe to the latitude of the given place, art. 189. bring that place to the ftrong brass meridian, and set the horary index to XII, fcrew the quadrant of altitude to the zenith of the horizon, and bring it to the brafs meridian, you will then at one view fee the fun's meridian altitude on every degree of the fun's declination for the whole year, cut by the graduated edge of the quadrant of altitude, on the dotted parallels; thefe dotted parallels at the fame inftant alfo cut the edge of the broad paper circle now reprefenting the horizon, in the point of the compais or amplitude, on which the fun is feen to rife on the east, or to fet on the west fide of the horizon, for every degree of declination throughout the year.

 $M_3$ 

Elevate

If

If you trace any of those parallels to the ecliptic line, you have the fun's place when he is upon that declination, and thence the day and month upon the horizon.

Alfo, the knowledge of the fun's place in the ecliptic line, fnews the fun's declina-. tion for that time amongst the dotted parallels.

# PROBLEM XL.

To shew at one view upon the terrestrial globe the length of the days and nights at any particular place, for all times of the year.

258. Rectify the globe to the latitude of the place, art. 189. and the broad paper circle will reprefent the horizon: and the upper part of the dotted parallels of declination, which are here alfo parallels of latitude, will reprefent the diurnal arches.

Whence we may obtain the number of hours each of them contains, which is the folution of the problem. To illustrate which,

Elevato

Elevate the globe to the polition of a right sphere, art. 214. and you will, with one glance of the eye, fee that all the dotted parallels of declination, as well as the equator itfelf, are cut by the horizon into two equal parts.

Therefore the inhabitants on the equinoctial line have their days and nights twelve hours long; that is, the fun is never more nor ever less than twelve hours above their horizon, during his apparent paffage, from the tropic of Cancer to the tropic of Capricorn, and thence to Cancer again.

All the fixed ftars have the fame apparent motion to the equatorial inhabitants; that is, they rife and fet, continue above, and are depressed below, the horizon of any place upon the equator, exactly twelve hours.

Raife the north pole of the globe a few degrees of latitude at a time, and you will fee the diurnal arches will increase in length. until the pole is elevated to  $66\frac{1}{2}$  degrees above the horizon : then the parallel of the fun's greatest declination will be as far from the equator as the place itself is from the pole; and this parallel is the tropic of Can-M 4 cer,

cer, which will just touch the horizon in the north point.

And on the contrary, we may observe, that the fouthern parallels of declination continually shorten, as the northern ones lengthen, until they come to the tropic of Capricorn.

Rectify the globe to the latitude of London  $51\frac{1}{2}$  degrees north : when the fun is in the tropic of Cancer, the day is about  $16\frac{1}{2}$ hours; as he recedes from thence, the days fhorten, as the length of the diurnal arches of the parallels fhortens, until the fun comes to Capricorn, and then the days are at the fhorteft, being of the fame length with the nights, when the fun was in Cancer, viz. about  $7\frac{1}{2}$  hours.

Rectify the globe to the altitude of the northern polar circle, and you will find, when the fun is in Cancer, he touches the horizon on that day without fetting, being completely twenty-four hours above the horizon: and when he is in Capricorn, he once appears in the horizon, but does not rife for the fpace of twenty-four hours; when he is upon any other parallel of declipation, the days are longer or fhorter, as that

that parallel is nearer to, or farther from, the equator.

Elevate the globe to the latitude of 80 degrees north, at which time let the fun's declination be 10 degrees north, he then apparently feems to turn round above the horizon without fetting, and never fets from this point to Cancer, until in his return, after he has again paffed this parallel of declination.

In the fame manner, when his declination is 10 degrees fouth, he is just feen at noon in the horizon, and disappears from that time in his foutherly motion, till his return to the fame point.

Elevate the north pole to 90 degrees, or in the zenith, then the globe will be in the position of a parallel sphere, (art. 210.) and the equinoctial line will coincide with the plane of the horizon : confequently all the northern parallels are above, and all the fouthern parallels below the horizon; therefore the polar inhabitants, if any there be, have but one day and one night throughout the year; their day, when the fun is in his northern; and their night, when he is in kis fouthern, declination.

suff heavens with these upon the globa.

out .

This method of rectifying the globe for north latitude holds good in fouth latitude alfo, by elevating the fouth pole.

# PROBLEM XLI.

To find what conftellation any remarkable flar, feen in the firmament, belongs to.

259. Bring the fun's place in the ecliptic for that day to the ftrong brafs meridian, and fet the horary index to that XII which is most elevated, the celessial globe being rectified to the latitude, turn the globe till it points to the present hour; and by the help of the mariner's compass, and attending to the variation, which at London is between 20 and 21 deg. from the north, westward, set the north pole of the globe towards the north pole of the heavens.

The ftar upon the globe (if you conceive yourfelf in the center,) which directs towards that point in the heavens, in which the ftar you want to know is feen, is the ftar required.

At the fame time, by comparing the ftars in the heavens with those upon the globe, the

the other stars and their constellations may be easily known; whereby you will be enabled, any star-light night, to point out many of those stars called correspondents to various places on the earth.

#### PROBLEM XLII.

To find at what hour any known ftar passes the meridian on any day in the year.

260. Rectify the globe to the latitude, (art. 189.) and fet the artificial fun to his place in the ecliptic: bring its center under the ftrong brass meridian, and fet the horary index to XII; then turn the globe till the ftar comes to the meridian; and the horary index will point upon the equator to the hour on which that ftar will be upon the fouth part of the meridian.

If you turn the globe on till the center of the artificial fun is under that graduated fide of the brafs meridian, which is below the elevated pole, all those stars, which are then cut by that fide of the meridian above the faid pole, will pass the meridian at midnight,

PROBLEM

#### PROBLEM XLIII.

To find on what day of the year any ftar passes the meridian at any proposed hour of the night.

261. Bring the ftar to the ftrong brass meridian, and fet the horary index to the proposed hour; then turn the globe till the index points to XII, and that degree on the ecliptic, which is cut by the meridian, is the fun's place, against which, in the kalendar upon the broad paper circle, is the day of the month.

#### PROBLEM XLIV.

To trace the circles of the fphere in the ftarry firmament.

262. We shall folve this problem for the time of the autumnal equinox; because that intersection of the equator and ecliptic will be directly under the depressed part of the meridian about midnight; and then the opposite intersection will be elevated above the horizon; and also because our first meridian

ineridian upon the terrestrial globe passing through London, and the first point of Aries, when both globes are rectified to the latitude of London, and to the fun's place by problem XII, art. 189, 192. and the first point of Aries is brought under the graduated fide of each of their meridians, we shall have the corresponding face of the heavens and the earth represented, as they are with respect to each other at that time, and the principal circles of each sphere will correspond with each other.

The horizon is then diftinguished, if we begin from the north and count weftward, by the following constellations; the hounds and waist of Bootes, the northern crown, the head of Hercules, the shoulders of Serpentarius, and Sobieski's shield; it passes a little below the feet of Antinous, and thro' those of Capricorn, through the Sculptor's frame, Eridanus, the star Rigell in Orion's foot, the head of Monoceros, the crab, the head of the little lion, and lower part of the great bear.

The meridian is then represented by the equinoctial colure, which passes through the flar marked *s* in the tail of the little bear, under

under the north pole, the pole ftar, one of the ftars in the back of Caffiopea's chair marked  $\beta$ , the head of Andromeda, the bright ftar in the wing of Pegafus marked  $\gamma$ , and the extremity of the tail of the whale.

That part of the equator, which is then above the horizon, is diffinguished on the western fide by the northern part of Sobieski's shield, the shoulder of Antinous, the head and vessel of Aquarius, the belly of the western fish in Pisces; it passes through the head of the whale, and a bright star marked  $\delta$  in the corner of his mouth, and thence through the star marked  $\delta$  in the belt of Orion, at that time near the castern fide of the horizon.

That half of the ecliptic which is then above the horizon, if we begin from the western fide, prefents to our view Capricornus, Aquarius, Pisces, Aries, Taurus, Gemini, and a part of the constellation Cancer.

The folftitial colure, from the western fide, passes through Cerberus, and the hand of Hercules, thence by the western fide of the constellation Lyra, and through the dragon's

dragon's head and body, through the pole point under the polar star, to the east of Auriga, through the star marked n in the foot of Castor, and through the hand and elbow of Orion.

The northern polar circle, from that part of the meridian under the elevated pole; advancing towards the welt, paffes through the fhoulder of the great bear, thence a little to the north of the ftar marked  $\alpha$  in the dragon's tail, the great knot of the dragon, the middle of the body of Cepheus, the northern part of Caffiopea, and bafe of her throne, through Camelopardalus, and the head of the great bear.

The tropic of Cancer, from the weftern edge of the horizon, paffes under the arm, of Hercules, under the Vulture, through the goofe and fox, which is under the beak and wing of the fwan, under the ftar called Sheat, marked  $\beta$  in Pegafus, under the head of Andromeda, and through the ftar marked  $\phi$  in the fifth of the conftellation Pifces, above the bright ftar in the head of the ram marked a, through the Pleiades, between the horns of the bull, and through a group, of ftars at the foot of Caftor, thence above a ftar

a ftar marked 3, between Caftor and Polluz, and fo through a part of the conftellation Cancer, where it difappears by paffing under the eaftern part of the horizon.

The tropic of Capricorn, from the western fide of the horizon, passes thro' the belly, and under the tail of Capricorn, thence under Aquarius, through a star in Eridanus marked c, thence under the belly of the whale, through the base of the chemical furnace, whence it goes under the hare at the feet of Orion, being there depressed under the horizon.

The fouthern polar circle is invisible to the inhabitants of London, by being under. our horizon.

To find the time of the fun's entry into the first point of Libra or. Aries; and thence that point in the equator to which the fun is vertical at either of those times.

263. This requires the knowledge of a meridian that shall pass through that point in the equator, to which the sun is vertical at the times of equinox; but as this point is

is variable, a fixed meridian must be first obtained.

In Anno Domini 1753, the late Rev. Dr. Bradley observed the fun to enter Libra September 22d. 10 h. 24 min. afternoon, new stile, at the Royal Observatory at Greenwich.

As the earth's diurnal motion is from welt to east, it causes all places to the east of any other place to pass first under the fun; therefore when the meridian of Greenwich passed under the fun that day, he was not then arrived at the intersecting point of the earth's equator and celessial ecliptic, but wanted 10 h. 24 min. which is equal to 156 degrees.

Whence the fixed or first meridian fought is thus obtained, and lies 10 h. 24 min. in time, or 156 equatorial degrees west of the Royal Observatory at Greenwich.

This meridian is marked by a dotted line on our new terrefitial globe; it passes thro' the great Pacific sea, and crosses one of the Isles of St. Bernard, and the Isle des Mouches.

The next thing to be confidered is the nearest mean length of a tropical year, which

is

is a determinate fpace or interval of time between the fun's apparent paffage from one point of the ecliptic, until he returns to the fame point again, or from one equinox to the fame again, be it either vernal or autumnal.

We take for our radix the autumnal equinox, anno 706 of the Julian period, which we call anno mundi 0, and compute from Thursday Oct. 25th, 0 h. 0 min. or noon, the sun being then supposed to be in the first point of Libra on the meridian before mentioned, and vertical to that point of the equator, which lies 156 degrees west of Greenwich.

And also in the meridian of Greenwich, Oct. 25th. 10 h. 24 m. upon the 298th day from the calends of January.

The tropical year thus reckoned exceeds the Egyptian year 5 h. 49 min. and is but 11 minutes fhort of the Julian year; fo much being annually allowed for the retroceffion of the equinox, confequently the mean length of a tropical year is 365 d. 5 h. 49 min.

We are induced to measure time by this quantity, because astronomers unanimously agree,

agree, that the earth paffes through all the figns of the ecliptic, to as to complete the circle in 365 d. 5 h. 49 min.

See the respective tables of Rudolphus, Tycho Brahe, Cassini, Sir Jonas More, Mr. Flamsted, Dr. Halley, Mr. Meyer, and Mr. Maskelyne; whereby it will appear that

	8	0	10	11

any tables extant.

N 2

And

And the difference between calculating downwards from the epoch A. J. P. 706, and calculating backwards in the modern practice, from the various epochs in the most celebrated tables, is, that in those last epochs, the 11 minutes of retrocession have not been considered.

	d.	h.	m.
From the vernal to the au- tumnal equinox	186	11	51
From the autumnal to the vernal equinox	178	17`	58
	265	5	40

The equinoxes regularly fall every year 5 h. 49 min. later in the day, than in the preceding year, and at the end of every annual motion of the earth, the equinoctial interfection changes its meridian weftward of that in which it fell the year before, juft 87 deg. 15 min.

Precepts for the use of the tables of retrocession and autumnal equinoxes.

264. First, Find the number of years from the radix : If the given year is before

fore the Christian Æra, subtract it from 4008; the remainder is the year from the radix.

Secondly, If any year fince the Christian Æra be given, add it to 4007, their fum is the year from the radix.

Thirdly, Collect the days, hours, and minutes of retroceffion, and autumnal equinoxes from the table, according to the number of years from the radix, in thoufands, hundreds, tens, and units; add thefe into two fums, the first will be the retroceffion, the second the time of the equinox in that meridian which lies 156 degrees west of Greenwich Observatory; to which add 10 h. 24 m. and you obtain the time at Greenwich.

This method will ferve for any other meridian alfo, if you add its difference in time from the fixed meridian.

Solar tropical years thus reckoned begin and end at the autumnal equinox, and all Julian years begin and end at the kalends of January \*.

N 3

In

\* The kalends of January begin from the noon of the preceding day; that is, from the noon of the day before the first day of January.

In comparing folar tropical years with Julian years, by which we ftill compute time, obferve, that the laft nine months of any folar tropical year answer to the first nine months of that Julian year with which it is compared; and that the first three months of the next succeeding tropical year answer to the three last months of that fame Julian year with which it is compared.

The 298th day from the kalends of January, which was Thursday in the 706th year of the Julian period, the fun entered Libra at noon; at which instant it was 10 h. 24 min. past noon at Greenwich.

In all calculations of autumnal equinoxes, we take the fame 298th day, or October 25th in the radical year 0, for our epoch.

And to gain the day of the month in which the equinox must happen fince the radix,

Add the number of days, hours, and minutes in the retroceffion, to the days, hours, and minutes of the equinox in the fixed meridian, and you obtain the Julian days and hours from the radix.

Add the epoch 298 to the days of the tropical reduction, and from their fum fubtrack

tract the intire days of the Julian reduction, the remainder is the number of days from the kalends of January old ftile; add thereto eleven days, and you obtain the number of days from the faid kalends of January new ftile; from which if you deduct the nearest less number in the table of months (which numbers express the last days of each month) the residue is the day of the fucceeding month.

But when the fum of the Julian reduction contains eighteen hours above entire days, it is a biffextile year; then one day more must be added to the entire Julian days before the fubtraction is made.

When there are no hours in the Julian reduction, that is the first year after a biffextile; if fix hours, the second; if twelve hours, the third; and when eighteen hours above entire days, it is the biffextile year.

And when the last refult exceeds 12 hours, add 1 to the days, and subtract 12 from the hours, and you change the time from astronomical to the civil reckoning.

To gain the time of the equinox on any other meridian, add the difference of meridians to the time found in the first meri-N 4 dian.

dian. Thus for London or Greenwich we add 10 h. 24 min. for Paris 10 h. 33 min. 20 fec. for Alexandria in Egypt 12 h. 25 min. &c.

# To gain the week-day.

265. Divide the days of the tropical reduction by 7; if o remains, it is Thursday; if 1, Friday; 2, Saturday; and 3, Sunday; and so on to 6, which is Wednesday, as in the table of week-days.

# To obtain the time of the vernal equinox.

266. First find the autumnal equinox for the same year in which the vernal equinox is required; and from it subtract 186 d. 11 h. 51 min. which is the distance in time from Aries to Libra; their difference will be the time of the vernal equinox required.

The day of the month, and week-day found as above, we obtain the literal character for that day as follows.

In the table of months stand the literal characters, that are placed against the first day

day of each month in any common almanack.

And whatever letter ftands against the first day of any month, the 8th, 15th, 22d, and 29th days of that month, are all characterifed with the same.

A circle of the 7 literal, or week-day characters.

The day of the month and week-day given, to find its literal character and dominical letter for that year.

267. A. D. 1772, the autumnal equinox will happen at Greenwich, September 22d, o h. 55 min. on a Tuesday.

QUERE, The literal character for that day and dominical letters for that year, it being biffextile?

The

The literal character for the 1st of September is F; so also is the 22d, and Tuesday in the present question. Look on the circle of week-day characters, call F Tuesday, G Wednesday, A Thursday, and so on to Sunday which falls upon D, the last of the two dominical letters for that year, serving from the intercalary day to the year's end.

The first dominical letter for leap-years is the next in the circle, and ferves for January and February, which in this example is E.

Therefore the two dominical letters for the biffextile year 1772 are ED new stile.

In any common year, the letter first found ferves for the whole year.

The dominical letter being known, to find on what day of the week any day in the year falls.

QUERE, What day of the week is the 20th day of March, A. D. 1772?

The literal character for the 1st of March is D, so is the 15th, and the 20th being 5 days more, if we count from D, which happens to be the dominical letter, to E Monday the 16th, we shall find B is Friday the 20th day of March, A. D. 1772, new stile,

-75-E

If the dominical letters were required for old flile, in these examples the first would be the 11th of September 1772, whose literal character is thus found, F the 1st day of September, and also the 8th, G the 9th, A the 10th, and B the 11th, and by the following calculus Tuesday, therefore A C are the dominical letters old stile, A. D. 1772.

the fun in the 1st point of Aries at Greenw. Mar. 19 13 4

We find the two equinoxes in the three next fucceeding common years, as in the preceding example, by the continual addition of 5 hours, 49 minutes.

By

By this method of calculation, we avoid any miftake that might happen with refpect to the intercalary day; becaufe we find the autumnal equinox first, and thence the vernal equinox, which always falls after the intercalary day, and also because tropical time has no biffextile years.

To reduce hours, minutes, and feconds of time, into degrees, minutes, and feconds of the equator.

13

We are now prepared to folve the latter part of the last problem, which is as follows.

# PROBLEM XLV.

To find all those places in which it is noon at the time of an equinox, as well as that point upon the equator, to which the fun is vertical at that time.

277. Having found the time of an equinox by the preceding, or any other method of calculation, as in the first example, we  $O_2$  find

find the fun entered the first point of Aries at Alexandria in Egypt, March 24th, 0 h. 32 min.

The 32 minutes of time reduced to the equator, are equal to 8 degrees.

Therefore bring Alexandria under the graduated fide of the strong brass meridian, and fet the horary index to XII upon the equator, turn the globe from west to east until 32 minutes of time, or 8 degrees of the equator have paffed under the horary index, where ftop the globe; then all those places under the faid graduated fide of the ftrong brafs meridian, will have noon, and that degree of the equator, which is then under the meridian, is the point to which the fun was at that inftant vertical, and is the interfecting point of the equator and ecliptic, or that terrestrial meridian, which governs the paffage of the first point of Aries for that year. well 38 1/200

equalor, to which the for is the

The

Celestial and Terrestrial Globes. 197 New Zeland ; all which place will have

The vernal equinox, A. D. 1772, will fall on the 19th day of March, at 13 h. 4 min. which reduced to the degrees and minutes of the equator, is equal to 196 degrees. of the equator, ...

278. Bring London to the ftrong brass meridian, and fet the horary index to XII, (in this cafe the graduated fide is the horary index) turn the globe from west to east until 13 h. 4 min. of time, or 196 degrees of the equator have passed under the horary index, where ftop the globe; the 196th degree of the equator will now be found under the graduated fide of the brafs meridian, and is that point on which the fun will be vertical at noon; at which inftant it will be 13 h. 4 min. palt noon at London or Greenwich.

The meridian paffing through this point, will be feen to pass a little eastward of Kamkatika through the Pacific Sea across the illand Dicerta, thence east of the isle Taumago, and through the western part of New
New Zeland; all which places will have noon at the inftant of that vernal equinox.

The autumnal equinox, A. D. 1772, will happen September 22, 0 h. 55 min. at London, the 55 min. being equal to 13 deg. 45 min. of the equator.

270. Bring London to the graduated fide of the strong brass meridian, and set the horary index to XII, turn the globe from west to east, until 55 minutes of time, or 13 deg. 45 min. of the equator have paffed under the horary index, where ftop the globe; here, as in the last example, the 13th degree and 45th minute is that point upon the equator to which the fun is vertical, and the meridian paffing through this point, lies under the graduated fide of the ftrong brass meridian; which passes over the middle of Greenland, and through the Atlantic Ocean to the east of Teneriffe, a little to the west of Ascension Island, and thence through the Ethiopic Ocean, at which places it will be noon at the time of this autumnal equinox. Here

Here it will be proper to give the reader a fhort account

Of the natural agreement between the celeftial and terreftrial fpheres; or, How to gain a perfect idea of the fituation and diffance of all places upon the earth, by the fun and ftars.

280. That part of the firmament, which is in the zenith of London, is perpendicular to half the globe of the earth; which half comprehends almost all the habitable land of Europe, Afia, Africa, and America, with their coasts, capes, land, and seas; fince under the other celessial hemisphere, which we do not sea at the same time, there are only very inconfiderable lands and isles.

The inhabitants of Great Britain and Ireland nearly fee the fame half of the firmament adorned with ftars and planets, which at all times fupply the place of an immenfe map of the world; and fhew our terreftrial hemisphere by the ftars, conveying the cor-O 4 respondent

respondent marks of the two continents to our fight and mind.

The fun, by his apparent daily motion, feems to defcribe a kind of fpiral, in pafling from one tropic to the other and back again, continually changing his declination, and every day defcribing a different parallel, art. 171.

Forty-feven of these diurnal parallels are drawn on our new terrestrial globe, art. 177, 178. between the tropics of cancer and capricorn, representing the parallels for every degree of the sun's declination.

Before the reader proceeds, he is defired in order to be perfectly acquainted with the caufe of the daily change in the fun's declination, to go back to art. 185, and read from thence to the 189th art.

Which being done, it will be eafy to conceive, that the fun being in any one of these parallels, must necessarily cash his perpendicular rays that day upon the heads of the inhabitants of those places through which that parallel of declination passes.

Note, Although these 47 parallels are here called parallels of declination, they are also

also parallels of latitude upon the terrestrial globe.

From these principles we obtain the fituation of those places, to which the fun is vertical every day in the year; we also find the time of that day at the place of any obferver, from whence looking at the fun, we may pronounce him to be over the heads of the inhabitants of divers cities and states, during the several hours of that day, and so on for every day in the year.

The fun being perpendicularly over any one of these distant cities or principalities, at the time of our observation, if a plumbline be held up between the observer and the fun, so as to pass through or before the fun's center, it will cut the visible horizon in a point, that will fix the bearing or passage in a right line from the observer to that place, upon which the fun is then vertical.

A point thus noted upon the vifible horizon may be feen at all times, and reprefent the fame bearing, independent of the fun and flars, and that in fuch a confpicuous manner as to render this knowledge always entertaining, ufeful, and interesting.

The

The stars at night perform the fame more copioufly, by pointing out to our fenfes the distance of many remote provinces, at one and the fame inftant of time, from our own zenith.

Hence we are in possession of a most extensive field, wherein we may correct and improve our aftronomical and geographical knowledge.

#### Examples of folar correspondents.

#### PROBLEM XLVI.

To find the folar correspondence, to a fixed point upon the earth, when the fun is feen by an obferver, fituated upon any other point of its surface.

## Example I.

281. Let the observer be in London (or in any of the country places within thirty miles of it) upon the 10th day of March, at 10 minutes past XI o'clock in the. morning. 255.02

QUERE,

QUERE, The place upon which the fun will be vertical at that time?

Rectify the globe, by bringing the 10th of March, engraved on the back of the ftrong brass meridian, to the plane of the broad paper circle; find the fun's place, against the day of the month in the kalendar, which will be about 20 deg. 10 min. in Pisces; seek these degrees and minutes in the fign Pifces upon the ecliptic line on the globe, and you will find it fall upon the fourth parallel of fouth declination: to all the inhabitants on this parallel, the fun will be vertical that day. Now bring 11 h. 10 min, on the equator to the graduated fide of the strong brass meridian, and you will find it cut the fourth fouthern parallel upon the city of Loango, on the western coaft of Africa.

Therefore if you look at the fun 10 minutes paft XI in the morning at London, you will then fee him at the inftant he is directly over the heads of the inhabitants of the city of Loango in Africa; at the fame time, your ideas are made fenfible of the comparative diftance, which you fee in the firmament between the zenith of London, under

under which you ftand, and the fun, which is then in the zenith of Loango; alfo if at the time of your obfervation, you caufe a plumb-line to be held up between you and the center of the fun, and caft your eye down towards the most distant part of your fensible horizon, the plumb-line will cut a point thereon, which, if remembered, will always shew you the true bearing or point of the compass, in a direct line from your fituation, to that of Loango.

This diftance and bearing may be nearly found by the globe thus :

Elevate the globe to the latitude of London, that the broad paper circle may reprefent your horizon; icrew the nut of the quadrant of altitude in the zenith, that is, upon 51 deg. 32 min. counted from the equator towards the elevated pole, bring London under that point, and lay the graduated edge of the quadrant upon Loango, which will cut the bearing 15 degrees, reckoned from the fouth towards the caft, or between the points SSE and SbE; now feparate the quadrant from the globe, and lay its graduated edge upon Loango and London, fo that the beginning of the graduation may lie upon one of the places, then tobar! the

the other will cut 56 degrees, which is equal to 3360 geographical miles, or 38921 English miles, the distance between London and Loango.

To elucidate this example, we shall trace the fun's verticity over that part of this day's parallel of declination, which is included between the rifing and setting fun at London for that day.

Imagine, as we have before supposed, an image of the sun to be painted upon the cieling of the room, directly over the terrestrial globe.

Let the globe be rectified to the 10th of March, place the center of the artificial horizon upon London, and bring it into a coincidence with the weft fide of the plane of the broad paper circle, now reprefenting the edge of the earth's illuminated dife; we fhall then have the position of the earth with respect to the fun for that day; when the inhabitants of London will be leaving the twilight, and passing into the first point of day, or fun-rising, at about 18 minutes pass the first point of day, or fun-rising, at about 18 minutes pass the first point of the hour line under the equator; at this time,

time, the meridian will likewife crofs the fourth parallel of fouth declination, in the Indian ocean, between the island of Sumatra and the Maldive Isles; if we look upon the fun that morning at the instant of his rifing. we shall fee that his distance from our zenith will then be go degrees, he being in our horizon, which is equal to 5400 geographical or 6155 English miles, the distance from London to that part of the Indian Sea : turn the globe from west to east, until 8 h. 12 min. are under the horary index, which in this cafe is the strong brass meridian, and it will cut the isle Macarenhas, to which the fun will then be perpendicular; at 1 past IX he will be perpendicular to the coaft of Zanguebar, his central ray paffing between Monibacca and Pemba; thence it passes over the kingdoms of Monomugi, Macoco, Congo, &c. until he is perpendicular to the city of Loango, upon the western coast of Africa, at 11 h. 10 min. the fame morning; immediately after which, his perpendicular rays are abforbed in the Ethiopic Ocean, over which he is 3 h. 22 min. in passing to Fort St. Lucar, on the eastern coast of America, at 32 minutes paft II in the afternoon ; thence he proceeds to

to fend forth his perpendicular rays over the heads of the inhabitants of Brazil, acrofs the vaft country of the Amazons and Peru, in the decline of our evening, until his arrival over Cape Blanco on the western fide of South America, a little before he fets to the inhabitants of London, which is about 40 minutes past V o'clock.

#### EXAMPLE II.

anoth date school guild boat

לייה רוכי, שניי ייתורי אוויי

ומידין אין אמפורבי אי אייט ביישני

282. Every rectification being obferved as in the first example; Q. What is the place upon which the fun is a correspondent at 48 minutes past VI in the evening of the 18th of May, the fun's place being about 17 deg. 40 min. in Taurus, or nearly vertical to the 17th parallel of north declination on that day? Turn the globe from west to east, until London has passed the strong brass meridian, and stop when its graduated side is directly over 6 h. 48 min. asternoon, and it will cut the 17th parallel of north declination, the city of Acapulco on the western coast of Mexico, over which the fun will then be vertical.

EXAMPLE

# Example III.

Ra shadi

283. Let the observer be at Cape Clear on the western coast of Ireland, on the 16th day of July, at 54 minutes past VIII in the SOUGH ACHERICS morning.

QUERE, The place upon which the fun will then be vertical?

The fun's place being in the 24th degree of Cancer, which on the globe falls upon the 21st parallel of north declination,

Bring Cape Clear to the graduated fide of the ftrong brass meridian, and fet the horary index to XII, turn the globe till 8 h. 54 min. amongst the morning hours are under the horary index, and you will find the graduated fide of the ftrong brass meridian to cut the 21st parallel of north declination npon Farrat in Nubia, on the western coast of the Red Sea.

#### EXAMPLE IV.

284. Let the observer be at Rome on the 20th day of November, at 37 minutes past X in the morning.

QUERE, The place upon which the fun will be vertical at that time?

The

The fun being about 281 degrees in Scorpio, which fails to the fouthward of the 20th parallel of fouth declination,

Bring Rome to the graduated fide of the ftrong brass meridian, and set the horary index to XII, turn the globe to have 10 h. 37 min. under the horary index, and the faid graduated fide will then cut, under the 20th parallel of fouth declination, the city of Sofala in the kingdom of Quiteri, to the fouth of Monomotapa, on the eastern coast of Africa.

We apprehend these four examples are fufficient to give the reader a clear idea of the folar correspondents to all places within the torrid zone, and to enable him to difcover fome thousands more.

Although we can have but one folar correspondent at the fame time, yet, as in the first example, we can trace him through his diurnal parallel for every hour and minute of the day, and fo alfo upon every day in the year.

Nothing can be eafier or more intelligible than this method of improving the mind, by representing to the eyes the diftance from our own zenith to that of every fpot ot.

P

of land and fea within the tropics; when at every fingle obfervation we have it alfo in our power to note the bearing of each of these places upon our visible horizon, which may be referred to, at all times, when the fun is not in that parallel.

Let us now change the scene, and proceed from the consideration of the sun, to that of the stars; which will prefent to our view a copious field of geographical knowledge; many of these may be seen at one and the same instant of time, when they are in the zenith of so many different places upon the earth, and then immediately afterwards remove from that designation, to give place for a great number of others.

## Of the celeftial correspondents.

285. The knowledge of the celeftial correfpondents difcovers a new fyftem of aftronomical geography. The perfect agreement between the celeftial and terreftrial fpheres conflitutes this fyftem; which may with very little trouble be underftood, by making the ftudy of one a guide to the knowledge of the other;

other; the object of this correspondence is the continual variation between the parts of the celestial and terrestrial spheres.

Geography alone being eafier than aftronomy, has generally a particular place in the education of young fludents, who feldom leave their juvenile fludies without gaining fome idea of the four quarters of the world, a flight notion of the fituation of places with respect to each other, and a fketch of the principal empires; but generally without any application to the terreftrial, and fearce ever a comparison of that with the celeftial globe; and without feeling a lively curiofity to become acquainted with thefe neceffary and improving branches' of feience.

To facilitate the fludy of geography, it has always been neceffary to lay maps and charts before a pupil, which are generally feparate-plans of different countries. But what idea do thefe afford of the vaft extent of the earth, of its fpherical form, or of the proportionable diffances, real bearings, &c. of the empires, kingdoms, and flates on the habitable part of our terreftrial globe?

P 2

How

2 M. Sugar

How much more intelligible and just are the proportionable distances of the fixed stars, when compared with the natural distances of the several places upon the earth, over which they dart their perpendicular rays; thereby conflictuting this new system of astronomical geography, by ocular demonstration? They are faithful testimonies of the vast extent of the universe, and they declare the distance, bearing, and situation of all places upon the earth.

By these means, together with the affistance of maps and charts, such a copious and clear idea of geography will be attained, and its natural principles so firmly established, as never to be erased.

The confequences to be drawn from these principles are entirely in favour of the harmony between the celestial and terrestrial spheres.

Of the passage or transit of the first point of Aries over the meridian.

286. This point determines the apparent daily motion of the heavens, and fixes the continual difference in the course of the sun and stars.

The

The knowledge of that particular point on the terrestrial equator, where its interlection with the celeftial ecliptic happens to fall at the time of a vernal equinox, points out that place upon the earth to which the fun is vertical at that time; and from the knowledge of this we obtain the time of its passage over any meridian upon the globe, for every day of the year.

The conformity of the degrees of right ascension, with those of terrestrial longitude, happens but upon one moment of the 24 hours, in a natural day; when the first point of Aries is on the meridian of London, the first degree of right ascension is on this meridian allo; and the fignal to confirm this is, when a ftar of the fecond magnitude marked y near the extremity of the wing of Pegafus, is upon the meridian; at that inftant, the equinoctial colure will be upon the meridian also; for this colure passes through the first point of Aries and that ftar.

This is the moment, in which each of the 360 degrees of right ascension in the celestial sphere, is perpendicular to every like degree of terrestrial longitude; at which P 3 time

time there is a perfect parallelism and perpendicular correspondence of all the circles, points, and lines, in both spheres.

To this we have paid a particular regard, in the conftruction of our new globes, by numbering the degrees on the equator of the terreftrial globe, with an upper row of figures in the fame direction, as those of right ascension are numbered upon the celeftial globe.

If from that inftant of time, when the ftar  $\gamma$  of Pegafus is upon the meridian, we conceive the ftars to be immoveable, and that we, together with the globe of the earth, are turned from weft to east upon the equatorial axis, we fhall perceive our own meridian to pass fucceffively under every degree and ftar on the celeftial equator.

287. And that the reader may thoroughly understand what is meant by this uniformity in the two spheres, let him imagine the celessial globe to be delineated upon glass, or any other transparent matter, which shall invest or surround the terrestrial globe, but in such a manner, that either may be turned about upon the poles of the world, whils the other remains sixed; and

and suppose the first point of Aries, on the investing globe, to be placed upon the first point of Aries on the terrestrial globe, (which point is in the meridian of London) they will then reprefent that fituation of the heavens and the earth, we have been just describing, on that instant, when the first point of Aries is upon the meridian; and then every ftar on the celeftial will lie upon every particular place of the terrestrial globe, to which it is a correspondent; each star will then have the degree of its right ascension directly upon the corresponding degree of terrestrial longitude; their declination will also be the fame with the latitude of those places upon which they lie.

Now if the reader conceives the celeftial investing globe to be fixed, and the terrefirial globe to be gradually turned from west to east, he will readily understand, as the meridian of London passes from one degree to another under the invefting fphere, that every ftar thereon becomes a correfpondent to another place upon the cach; and fo on, until the earth has completed one diurnal revolution, or till all the ftars, by their apparent daily motion, have passed over P 4 every

every meridian of the terrestrial globe. Hence arifes an amazing variety in the harmony of both spheres.

If the fun and a ftar pais the meridian on any particular day, the next day the ftar will precede the fun about 4 minutes; in two days the acceleration of the ftar with respect to the fun will be about 8 minutes, in 4 days 16 minutes, in 8 days 32 minutes, and in fifteen days the apparent motion of the ftar will be accelerated one hour, whils the fun, with respect to the ftar, will feem to be retarded one hour; in one month the ftar will be two hours before the fun, in three months fix hours, in fix months twelve hours, and in one year twenty-four hours.

So that a year after the fun and ftar have crofied the meridian together, they will meet again nearly at the fame time; but the ftar, inftead of feeming to make 365 revolutions, will have made 366, one more than the earth to the fun in a year.

The right alcention of the first point of Aries, is the complement of the fun's right alcention to 360 degrees of the equator, or to the 24 hours of a natural day : this is the point

point, from which the right alcention of the fun, stars, and planets is always reckoned.

The reader will pleafe to obferve, that in fpring and fummer, the first degree of right afcension, which is the first point of Aries, comes to the meridian with us before noon; there are no stars then visible in the night, but those which follow the first point of Libra; that is to fay, those stars which have more than 180 degrees of right afcenstion: in autumn and winter those stars are visible in the night, which follow the first point of Aries, having less than 180 degrees of right afcension.

Observe also, that the interval between the passage of the first point of Aries over the meridian of any place, and that of the first point of Libra over the same meridian, is not 12 complete hours, but only 11 hours 58 minutes, to which attention must be paid, least these two minutes should be mistaken.

By the passage of the stars over the meridian, we are taught the knowledge of those degrees of the equator, which are then rising and setting; for that degree which is fetting

fetting precedes that on the meridian 90 degrees, or fix hours; and 180 degrees or twelve hours that which is rifing; and that degree of the equator, which is on the meridian under the elevated pole, is 180 degrees diftant from that point of it which is pafling the meridian.

#### PROBLEM XLVII.

To find the time of the right afcenfion of the first point of Aries upon any meridian.

288. We have already fhewn by an eafy calculus, how to find the times of equinox to any meridian, but we have not yet fhewn their application to the right alcention of the first point of Aries.

The diurnal difference of right afcention, at the time of a vernal equinox, is 3 min. 38 fec. which we have formed into a table, entitled, " The horary difference in the " motion of the first point of Aries at the " time of a vernal equinox;" to which is annexed, " A table of the difference of the " paffage

" paffage of the first point of Aries over the meridian for every day in the year."

# The use of the tables of right ascension.

289. Having found the time of any vernal equinox, and transferred it from the fixed to your own meridian by the addition of your meridian diffance,

Take out of the table of horary differences, the motion answering to the hours and minutes of the time of the vernal equinox, and their sum will be the time of the passage of the first point of Aries over that meridian; the day on which, but before, the equinoctial intersection happens.

N.B. In taking out the numbers from this table, reject the thirds, if they are under thirty; if they exceed thirty, add one to the minutes found in the table.

A. D. 1769, the vernal equinox falls on March 19th, 19 h. 37 min.

The right afcention of the first point of Aries, thus found for the day on which the equinox happens, holds good for the whole year, and is to be added to the difference of the passage of the first point of Aries over the meridian found against the day of the

the month; and their fum will be the time of day when the first point of Aries will pass the meridian.

Observe when the equinox falls on the 19th day of March in a year which is not biffextile, to seek the day of the month in the right hand column of the table; and when it falls upon the 20th day of March, seek the day of the month in the left hand column, over which in either case, and under the name of the month, you have the proper difference of right ascension to be added to that found above for the day of the equinox.

In biffextile years, feek the day of the month in the left hand column, to the end of February, and for the intercalary day, or 29th of February, take out the difference of right alcention antwering to the first of March, after which to the year's end feek the day of the month in the right hand column.

Having thus found the right afcention of the first point of Aries for any day in the year, add thereto 11 h. 58 min. and you obtain the time of the right afcention of the first point of Libra.

These four examples are quite sufficient, if the reader compares them with the tables and precepts.

In the 42d and 43d problem, art. 260, 261. we have fhewn how to find the hour that any known ftar comes to the meridian; and allo to find the time of the year any ftar paffes the meridian at any hour proposed, but in that place we were not prepared to apply the right ascension of the first point of Aries, so properly for an observation of the stars, as by the following

#### PROBLEM XLVIII.

To find the time of the right afcenfion of any ftar, upon any particular meridian, on any day in the year.

290. First find the time of the right afcention of the first point of Aries, art. 288. by problem 47, agreeable to your own meridian.

Then apply to the celeftial globe, and bring the given far under the graduated fide of the ftrong brass meridian, which will cut

cut its right afcenfion, or rather its diftance in time or degrees, upon the equinoctial; add this quantity expressed in time to the right afcension of the first point of Aries, and you will obtain the time of the passage of that star over the meridian very near the truth: Thus,

The ftar marked  $\gamma$  in the head of Draco, will have 268 degrees, or 17 h. 52 min. of right alcenfion or diftance from the first point of Aries, art. 276; which added to the right alcenfion of that point for the 13th day of July, A. D. 1772, gives the true time of its right alcenfion that evening : at 10 h. 12 min. this ftar will be over the heads of the inhabitants of London at that time, its declination being 51 deg. 32 min. equal to the latitude of this capital city.

Note, In this method of working, when the hours exceed 24, deduct 24 hours therefrom, and you obtain the true time fought.

PROBLEM

## PROBLEM XLIX.

To rectify the celeftial globe for any time in the evening of any day in the year, by the knowledge of the time when the first point of Aries shall pass the meridian that day.

291. As the degrees and hours upon the equinoctial line on our new globes, are numbered from the first point of Aries,

First find the right ascension of that point by problem 47, art. 288. for the given day, and rectify the globe to your latitude, art. 180. then bring the first point of Aries upon the globe, under the graduated fide of the ftrong brass meridian, and set the horary index to the hour and minute of the passage of Aries o, first found : turn the globe until the given hour is under the horary index, and place it due north and fouth by the mariner's compass, attending to the variation of the needle. and you will have a perfect representation of the ftarry firmament, not only for that instant, but as long as you please to apply PROBLEM yourfelf

yourself to the knowledge of the stars that evening, by only moving the globe to any other minute under the horary index as the time advances.

Thus on the 25th of February, A.D. 1770, about 46 minutes after V. in the evening, the star called Al-debaran, or the Bull's-eye, will be upon the meridian of London, or places adjacent; about VI o'clock that evening, Orion will begin to pass the meridian, and prefent a glorious view to the eyes of the observer, there being fo many eminent stars in that constellation, then fucceflively passing over the meridian until  $\frac{1}{2}$ past VII; all the stars in Auriga, or the Charioteer, will be paffing the meridian at the fame time ; after which Canis Major will fucceed with Syrius, the Dog-star, at the fide of his jaw; then Canis Minor and Gemini or the Twins will follow, and fo on for the remainder of the night. This appearance may be observed several months, but at different hours in the night, which may be found by this problem.

Also on the 8th of May in the fame year, the first point of Aries will pass our meridian at 20 h. 58 min. 29 sec. but if we reckon Q 2 the

the hours from midnight, at 58 minutes past VIII in the morning, at which time no stars can be feen; therefore we must have recourse to the right ascension of the first point of Libra, which is thus obtained,

me and the second second	h.	min.	fec.	
To the right alcention of the first of Aries	20	58	29	Margaro,
add	11	58	0	there
When the hours exceed 24 (ub. )	32	56	29	a gran
tract therefrom	.24-	0	0	inimi/il
The right alcention of the first point of Libra, A. D. 1770,	8	56	29	in the
May 8th, at		05-	~	evening.

Now in the precept to this problem, read Libra instead of the word Aries, and the rule will hold good in this as well as in the first case. Therefore.

Bring the first point of Libra to the graduated fide of the strong brass meridian, and fet the horary index to 56 minutes past VIII in the evening, turn the globe until the horary index points to 10 minutes past X o'clock, and you will find the ftar called Spica Virginis, being that in the car of corn the holds in her hand, a ftar of the first magnitude marked a, upon the meridian at that

that time. If you then look at the firmament, you will fee the conftellations Cancer, Leo minor, Leo major, the great Bear, with the head and wings of Virgo, on the weftern fide of the meridian; and on the eaftern fide thereof, the Ballance, Scorpio, Bootes, Hercules, &cc. fucceflively following the first point of Libra in their paffage over the meridian.

# The correspondence of the fixed ftars.

292. Before we attempt an obfervation of this kind, a fignal or warning flar must be first obtained; that is, fuch a star is to be fought, as shall have the same or nearly the same quantity, either in degrees or time of right ascension, reckoned from the first point of Aries, as the place, over which any other star shall then happen to be a correspondent, shall have of longitude, reckoned eastward of London.

It has been fhewn, that declination in the celeftial, and latitude on the terreftrial, globe, mean one and the fame thing, both being measured by their distance from the equator;  $Q_3$  confe-

confequently, if the declination of any ftar is equal to the latitude of any place, that ftar, by a line conceived to be drawn from it to the center of the earth, will defcribe the parallel of that place; whence it becomes a correspondent, not only to that particular place, but also to all those places which lie in the same parallel of latitude, by passing perpendicularly over them all once every 24 hours. But as a preparation, we must first shew, by the following problems, how to find those places to which any star is a correspondent, and those stars which are correspondents to any place.

## PROBLEM L.

#### To find all those places to which any ftar is a correspondent.

293. First find the declination of the ftar on the celestial globe by problem V. art. 55. and remember whether it be north or fouth; count the fame number of degrees upon the strong brass meridian of the terrestrial globe the fame way from the equator, and note the place by holding the edge of a card thereto; turn the globe from east to west, and

and all those places which pass under that point, will be correspondents to that ftar, because they will be in the line passing from the center of the earth through the very place upon its furface, to which the ftar is at that time vertical. - Thus,

The declination of the ftar marked  $\gamma$ , in the head of Draco, is 51 deg. 32 min. equal to the latitude of London; therefore this brilliant star of the fecond magnitude may be called the ftar of this metropolis, without being deprived of its own name; it may likewife take the name of any other place in the parallel of London.

The reverse of this problem being to find all the flars which are correspondents to any place, is fo eafy as to require no farther explication, than that of applying first to the terrestrial globe.

The apparent diurnal motion of one star only, will fucceffively fhew its perpendicularity to various countries, as will appear by

The destroit of a cur con condent flar with the densition Braces is for degit 22 trains interest to the part is a set of the part of here the trainers of or gloups

Q 4

at a battantany offered a A general

A general defcription of the paffage of the ftar marked  $\gamma$  in the head of the conftellation Draco, over the parallel of London.

294. This eminent ftar traces the parallel of London, and is a ftar of perpetual apparition to the inhabitants of the Britannic Ifles; it comes upon the meridian of London with the 268th degree of right ascension, and is at that time directly perpendicular to, or over the heads of, the people in this city, two minutes of an hour after its warning star marked k in the milky way, has passed the meridian.

Note, This star marked k is the southermost of a group of five stars, situated between the shoulder of Serpentarius and Sobieski's shield, which in the simament appear in the form of a Roman V, as may be seen upon the globe.

The declination of our correspondent ftar  $\gamma$  in the head of Draco, is 51 dcg. 32 min. equal to the latitude of London; with which apply to the terrestrial globe, and bring London to the graduated fide of the strong bras

brafs meridian, and fet the edge of a card thereto, holding it to the brafs meridian with your right hand, while you gradually turn the globe from weft to eaft with the other hand, and that point of the card which is upon the globe will then reprefent the interfection of that line upon the furface of the earth, which we have fuppofed to pafs from the center of the earth to the ftar; and as this point, though at reft, paffes over the parallel of London upon the globe, fo does the central ray, proceeding from the ftar, really pafs over every point of land, and fea, upon that part of the earth which is circumferibed by the parallel of London.

Thus you will fee the flar marked  $\gamma$ , in the head of Draco, pafs from London over the road to Briftol, and dart its perpendicular rays upon that city; then croffing the fea, it reaches Ireland between Kinfale and Cork, and leaving that kingdom, will fhine over the Atlantic Ocean, until it is perpendicular to the north cape of Newfoundland; whence it will be vertical to Efkimos, and pafs between lake Achona and the northern coaft of the gulph of St. Lawrence, then it will crofs St. James's Bay, Kriftino, &c. and
and pass westward over a vast space of land but little known to the Europeans ; thence it will leave the western coast of North America, to fhine upon the northern part of the Pacific Ocean, until it is perpendicular to feveral islands, one of which is called St. Abraham; it croffes the fouthern land of Kamkatska, and the island Sangalien; thence it becomes perpendicular to the continent near Telmen on the east fide of Mongales in Chinese Tartary, and so proceeds to cast its perpendicular rays over a vast country in Afia, being fometimes a zenith point to the Chinese, at other times to the Russian Tartars, and passing over Bielgorod, becomes vertical to Muscovy, Poland, Germany, and Zeland, and fo croffes the fea again to return to its perpendicularity over the city of London : all which is performed by the earth's diurnal motion in to thort a time as twenty-three hours and fifty-fix minutes.

When a beginner has been thus exercifed with the general passage of two or three principal stars over their correspondent parallels on different parts of the earth, his ideas will be so greatly improved, that maps and

and charts may then be laid before him with propriety, in order to confirm him in the knowledge of the particular parts of those very parallels, of which he has already attained a general idea upon the globe.

### PROBLEM LI.

To find a fignal, or warning flar, that shall be upon or near the meridian of an observer, at the time any known flar is perpendicular to any place on its corresponding parallel.

295. Bring the given place to the graduated fide of the ftrong brass meridian on the terrestrial globe, and it will cut the degrees of its longitude, reckoned eastward from London, upon the upper row of figures over the equator; then

Apply to the celeftial globe, and fet the given ftar under the graduated fide of the ftrong brafs meridian, which will cut the degree of its right afcention on the equinoctial.

MORITON,

Dir to be Va

If the fituation of the observer is west of the given place, subtract the terrestrial longitude from the right alcenfion of the ftar; if east, add the longitude, and move the celestial globe, till the fum or refidue: thereof is under the graduated fide of the ftrong brass meridian, and then that fide will be directly over those stars which are upon, or have just passed, or are not quite come up, to the observer's meridian, at the moment the given star is vertical to the place proposed; either of which will correctly answer the present purpose, and become the fignal or warning ftar; that upon its arrival on the meridian, will declare the given ftar to be vertical to the place affigned.

Thus let the observer be in or near London, and the bright star in Lyra, or the harp of the first magnitude be given, it is called Vega, and marked a: this star is a correspondent to the south west cape of the island of Sardinia in the Mediterranean.

The longitude of this cape from London is 9 degrees, and the right afcention of the ftar Vega is 277 degrees, as London is weft of Sardinia; 9 degrees fubtracted from 277 degrees, leaves 268 degrees of right afcention,

afcenfion, to which the celeftial globe being fet, the graduated fide of the ftrong brafs meridian will be found directly over the ftar  $\gamma$  in Draco, and also over a ftar of the fourth magnitude in one of the heads of Cerberus. These are eminent fignals, and both upon the meridian, when at the fame time the ftar marked  $\theta$ , in the knee of Hercules, will have passed the meridian about two minutes of an hour, and the ftar marked P, of the fourth magnitude in the milky way, will want about two minutes of an hour of coming to it.

Hence when the ftar marked  $\gamma$ , in the head of Draco, fends forth its perpendicular rays upon the city of London, the ftar Vega in Lyra will also be perpendicular to the S. W. cape of the island of Sardinia. At which time an observer at London will be fensible of the distance between the zenith of the two places, and may note the bearing of Sardinia from London upon his fensible horizon, to which he may refer at any time in the day. An observer at Sardinia may note the fame with respect to the distance and bearing of London from him.

To excite fludents who have an afpiring emulation to improve themfelves in this extenfive

tenfive fcience of geography and astronomy, the principal requisites whereby they may acquire universal knowledge, we shall proceed to illustrate this system of the natural agreement between the celestial and terrestrial spheres, by a few interesting examples.

### EXAMPLE I.

When the ftar marked  $\nu$  in the head of Draco is perpendicular to the city of London, the twelve following ftars may be feen from thence at the fame time, when they will also be perpendicular to as many places upon the earth.

296. The fignal or warning ftar is  $\gamma$  in the head of Draco, which comes upon the meridian with the 268th degree of right afcenfion; it will be vertical to the city of London two minutes of time, after the ftar marked k, in the milky way, near the equinox, has paffed the meridian, at which time the twelve following ftars will be vertical to the places they ftand againft:

The

The use of a warning star is to point out the true time of the phænomenon, which is to be first nearly found by obtaining the time of the right ascension of that star for the evening, on which the observation is intended to be made.

This table of correspondents was formed as follows:

The right ascension and declination of the stars was found in round numbers upon the celestial globe, and written in two columns, inclosing the names of the stars; the columns for the names of the correspondent places being left blank for their infertion afterwards :

Next, as the longitude on our new terreftrial globes is numbered both ways from the meridian of London, whatever the right afcenfion of the fignal ftar may happen to be, that point of the celeftial fphere is likewife confidered to be upon the meridian of London. Therefore,

To gain the longitude in the last column of the table, if the given stars were east of the fignal, the right ascension of the warning star was subtracted from the right ascension of the given star.

But

But the west longitude was obtained by fubtracting the right ascension of the given stars from that of the signal.

The reverse of this example is to find, what ftars will be perpendicular to any place upon the earth, a warning ftar being known, that shall be upon the meridian of an obferver, when the ftars to be fought shall be vertical to the places affigned, which the reader will eafily perform from what has been already faid.

When a ftar is known to be perpendicular to any affigned place, its correspondence to that terrestrial point may be equally affirmed, to all those who can see it at that instant from any part of the earth, or sea, they may then happen to be upon.

If an observer in Palmyra, another in the middle of the Mogul's empire, a third at Levata in Africa, and a fourth at Chapa in Mexico, should look at the star  $\gamma$ , in the head of Draco, the moment it is in the zenith of London, they will see its correspondence to that metropolis at one and the fame instant of time; their hour only will be different according to the difference of the meridians, as those places are structure either.

The

The fignal or warning ftar to each of these places, is the perpendicularity of that star expressed in the preceding catalogue of twelve ftars.

From the observation under either of these stars in the catalogue, may be seen the other twelve stars, when they are shining over the heads of the inhabitants of all the other countries therein named.

This conftitutes the fystem of astronomical geography before spoken of. It affords us a real assistance from the heavens, whereby we not only see the marvellous distances of a multitude of celestial bodies, composing that part of the universe, which we are permitted to behold; but it also enables us to comprehend the distances and bearings of the most remote countries from that point of the earth upon which we stand.

#### EXAMPLE II.

to antos o tas

Course in

297. When the bright ftar marked  $\beta$ , in the head of Caftor, is upon the meridian of London with the 110th degree of right afcenfion, the twelve following correspondents will be vertical to the places annexed.

## PROBLEM LII.

The phænomena of the harvest moon.

301. When the moon is at or near the full, about the time of an autumnal equinox, the rifes nearly at the fame hour for feveral nights together: this phœnomenon is called the harvest moon.

To account for this upon the celeftial globe, fet the artificial fun upon the first point

point of Libra, where the fun must neceffarily be at every autumnal equinox, and place the artificial moon upon the first point of Aries, where she must be, if a full moon should happen at that time.

Rectify the globe to the polition of a right fphere, art. 214. which answers to the inhabitants of the equator; bring the center of the artificial fun to the western edge of the broad paper circle, and the horary index in this case being the graduated edge of the ftrong brass meridian, will cut the time of the fun's fetting, and the moon's rising; hence it is obvious the moon will rise when the fun sets, which will be at VI o'clock, because they are both fupposed to be in the celeftial equator, but in opposite figns. Therefore on that day the same phænomenon will happen in all latitudes between the equator and either pole.

But as the moon's motion in her orbit, which we shall at prefent confider as coincident with the ecliptic, is about 13 deg. 10 min. every day, which retards her diurnal motion about 51 min. 56 fec. of time with respect to the first point of Aries, this daily difference as it relates to the fun is generally

generally reckoned at 48 minutes of time, or two minutes for every hour.

Let us now enquire upon the globe, what time the moon will rife the next night after the autumnal equinox, at which time the fun will have advanced one degree in Libra, and the moon 13 deg. 10 min. in Aries, which is 12 degrees more than the fun has done in the fame time: therefore place the center of the artificial fun upon the first degree of Libra, and the artificial moon on 13 deg. 10 min. of Aries, the globe being rectified as before to the polition of a right fphere, bring the artificial fun under the graduated fide of the ftrong brafs meridian, and fet the horary index to XII, turn the globe until the artificial fun coincides with the western fide of the broad paper circle, the horary index will shew he fets that evening at VI o'clock, and the globe being turned till the artificial moon coincides with the eastern fide of the broad paper circle, the horary index will shew the moon's rising that evening to be about 48 minutes past VI o'clock, with 5 degrees of amplitude northerly, as the is now entered into the northern half of the ecliptic.

71 332(22)

Now

Now elevate the north pole of the globe to the latitude of London, every other rectification remaining the fame, and bring the artificial moon to the eaft fide of the horizon, and the horary index will point to 20 minutes paft VI, her time of rifing; and her amplitude at that time will be about 8 degrees, three degrees more than at the equator the fame evening.

If we thus investigate the time of the moon's rising for two or three nights together before and after the autumnal full moon, it will be found nearly the fame.

The reafon is, that the full moons which happen at this time of the year, are afcending from the fouthern into the northern figns of the zodiac: whence the moon deferibes a parallel to the equator every night more northerly, which increafes her rifing amplitudes confiderably, and more fo as the latitude is greater, as in the prefent example; hence it is plain, that the nearer any celeftial object is to either pole, the fooner it afcends the horizon.

Every thing remaining as before, if we elevate the north pole of the globe to 66 ½ degrees, which is the latitude of the northern polar

polar circle, and bring the artificial moon to the east fide of the horizon, she will be found to rife about the fame time that the fun sets the evening after the autumnal full moon, which is about VI o'clock, at which time and place her amplitude will be about 13 degrees.

In this polition of the globe, if the artificial moon be removed 13 deg. 10 min. upon the ecliptic, which is her mean motion therein for one day, and fo on for fourteen nights together, the will be teen to rife within the space of one hour during that time, which will be clear on observing that half the ecliptic rifes at once.

It is remarkable that when the moon varies leaft in the time of her rifing, the diurnal differences are greateft at the times of her fetting.

What has been faid with respect to north latitudes is equally applicable to fouth latitudes.

In like manner the new moons in fpring rife nearly at the fame hour for feveral nights fucceffively, while the full moons rife later by a greater difference than at any other time of the year, becaufe at this time of

of the year the new moons are in the afcending, and the full moons in the defcending figns.

This phœnomenon varies in different years: the moon's orbit being inclined to the ecliptic about 5 degrees, and the line of nodes continually moving retrograde, the inclination of her orbit to the equator will be greater fometimes than at others, which prevents her hastening to the northward or defcending fouthward in each revolution with equal pace.

### PROBLEM LIII.

To find the time of the year in which a ftar rifes or fets cofmically or achronically.

302. The cofmical rifing and fetting of a ftar, is when a ftar rifes with the fun, or fets at the time the fun is rifing.

The achronical rifing or fetting of a ftar, is when a ftar rifes or fets at the time the fun is fetting.

Elevate the pole of the celestial globe to the latitude of the place, and bring the star

to the eaftern edge of the broad paper circle, and obferve what degree of the ecliptic rifes with it, which feek in the kalendar on the broad paper circle, against which is the day of the month whereon that star rifes cosmically,

Turn the globe till the ftar coincides with the weftern edge of the horizon, and that degree of the ecliptic which is cut by the eaftern fide, gives the day of the month when the ftar fets cofinically; fo likewife against the degree which fets with the ftar you have the day of the month of its achronical fetting, and if you bring it to the eastern fide of the horizon, that degree of the ecliptic then cut by the western fide of the broad paper circle fought in the kalendar, will shew the day of the month when the ftar rifes achronically.

# PROBLEM LIV.

To find the time of the heliacal rifing and fetting of a ftar.

303. When a ftar is first visible in the morning, after having been so near the sun as to be hid by the splendor of its rays, it is faid to rise heliacally.

01

When

When a ftar is immerfed in the evening, or hid by the fun's rays, it is faid to fet heliacally.

Elevate the pole of the celestial globe to the latitude of the place, bring the star to the eastern fide of the broad paper circle, fix the quadrant of altitude to the zenith, and apply its graduated edge to the western fide in such a manner that its 12th degree above the horizon may cut the ecliptic, the point opposite to this will be 12 degrees below the broad paper circle on the eastern fide, and is the fun's place in the ecliptic at the time a star of the first magnitude rifes heliacally; feek this point in the kalendar, or upon the ecliptic line on the globe, against which you will find the day of the year when that star rifes heliacally.

To find the heliacal fetting, bring the flar to the weftern fide of the horizon, and turn the quadrant of altitude on the eaftern fide, till the 12th degree cuts the ecliptic; its oppofite point is the fun's place, which fought either upon the kalendar or ecliptic line, gives the day of the year when the flar fets heliacally.

Stars

" See the Rep. Mr. Coffard's Hillory of Allorative, p. 15.

I. AL

Stars of the first magnitude, according to Ptolemy, rife or fet heliacally, when they are 12 degrees distant from the fun: that is, when the star is rising, the fun must be depressed in the perpendicular below the horizon 12 degrees, that the star may be far enough from the star's rays to be seen before he rifes.

- Stars of the fecond magnitude require the fun's depression thirteen degrees, and those of the third magnitude fourteen degrees, &c.

The manazil al kamer of the Arabian aftronomers, \* from Ulugh Beigh, published at Oxford 1665.

304. The manazil al kamer of the Arabian aftronomers, are XXVIII, they are fo called, i. e. the manfions of the moon, becaufe they obferved the moon to be in or near one of these every night during her monthly course round the earth: they are these that follow, to which upon the globe the Arabian characters are affixed, but omitted here for the want of an Arabian type.

I. Al

\* See the Rev. Mr. Coftard's Hiftory of Aftronomy, p. 19.

- I. Al Sheratân, these are the first and second stars of Aries, or the stars in the Ram's horns, marked  $\beta$  and  $\gamma$ , with I,  $\sigma$ , fignifying the first mansion of the moon, which the reader will please to remember once for all.
- II. Botein, the ftars in the Ram's belly according to Ulugh Beigh, by Bayer and on our globe e and p.
- III. Al Thuraiga, the Pleiades.
- IV. Al Debarán, the Bull's eye.
- V. Al Heb'a, the three ftars in the head of Orion.
- VI. Al Hen'ab, the ftar marked  $\xi$  in the left foot of Pollux.
- VII. Al Dira, the two bright flars, one in the head of Caftor, the other in Pollux, marked  $\alpha$  and  $\beta$ .
- VIII. Al Nethrab, the nebulæ, or group of stars in Cancer, marked e called by the Greeks  $\varphi_{alvn}$ , i. e. Præsepe.
- 1X. Al Terphab, the Lyon's eye marked µ.

X. Al

- X. Al Geb'ha, the ftar in the Lyon's mane marked ζ.
- XI. Al Zub'rab, the ftars in the Lyon's rump marked  $\vartheta$  and  $\vartheta$ .
- XII. Al Serphab, the Lyon's tail marked  $\beta$ , called Deneb al afad.
- XIII. Al Awwa, they are four stars in Virgo marked n 3 0 7.
- XIV. Simak al A'zal, the Virgin's fpike marked  $\alpha$ .
- XV. Al Gaphr, three ftars in the fkirt of the robe of Virgo marked  $\varphi$  : \*.
- XVI. Al Zubàna, that is Libra, the northern fcale is called Zubânab Al Shemali, and is the ftar marked  $\beta$ , the fouthern fcale marked  $\alpha$ , is called Zubânab al Genubi, Shemali fignifies northern, and Genubi fouthern, they are exactly mifcalled on the common globes of modern conftruction.
- XVII. *Al-Iclil*, thefe are the four flars in Scorpio marked  $\nu \beta \delta \pi$ .

XVIII. Al

XVIII. Al Kalb, the fcorpion's heart marked a more fully. Kalb Al Akrab, the word Antares, if it is not a corruption, has no fignification, and is therefore omitted.

- XIX. Al Shaulab, the Scorpion's tail, or the ftar marked λ. The word Lefath we have omitted, being another pronunciation of Lafab, the true name is Shaulab.
- XX. Al Náaim, these are eight stars in Sagittary, marked γ δ ε λ μ σ φ ψ;
  Ulugh Beigh makes them only three,
  i. e. γ σ ψ.
- XXI. Al Beldab, this is that part of the Horfe in Sagittary, where there are no stars drawn, and if there be any in that part of the heavens, it is thought they are only telescopic stars.
- XXII. Sad Al Dâbib, three ftars in Capricorn, marked  $\alpha \beta \nu$ .
- XXIII. Sad Al Bula, the ftar marked v in the hand of Aquarius.
- XXIV. Sad Al Suûd, the ftar's marked  $\beta$ and  $\zeta$  in Aquarius.

S 2

XXV. Sad

XXV. Sad Al Achbigab, three ftars in Aquarius marked  $\gamma \xi \theta$ .

XXVI. Al Pherg al Muhaddem, the ftars marked  $\alpha$  and  $\beta$  in Pegafus.

- XXVII. Al Pherg al Muåechir, these are two stars, one in the head of Andromeda, marked 3, the other in the wing of Pegasus, marked  $\gamma$ .
- XXVIII. Al Rifhâ, the ftar marked  $\beta$  in the girdle of Andromeda.

This is a division of the heavens, different from any thing the Greeks were acquainted with, and therefore was not borrowed from them.

### PROBLEM LV.

### To find a meridian line.

305. Bring the fun's place in the ecliptic on the celeftial globe, to the graduated fide of the ftrong brass meridian, and fet the horary index to that XII, which is most elevated; turn the globe, till the ftar marked  $\gamma$  in Caffiopea's hip, is under the graduated

duated fide of the strong brass meridian. with about 11 degrees of right afcenfion ; at which time the polar star, in the extremity of the tail of the little bear, will be above the pole, and upon the meridian alfo. If you find in this application of the globe. that the horary index points to any hour of the day, when the globe is rectified to the latitude of your fituation, turn the globe again, till the ftar marked , called Alioth, being the first in the tail of the great Bear, is under the graduated fide of the ftrong brass meridian, and then the polar star will likewife be upon the meridian, with about 191 degrees of right alcention, but under the north pole, and the horary index will point out the time of the night, when this phænomenon is to happen, before which you are to have the following apparatus properly prepared, that you may be ready to attend the observation, that is, to find your meridian line.

Sufpend two plumb lines, and let their weights be immerfed in water, to prevent their vibrating, but in fuch a manner that the ftring of one of them may be directly between the polar ftar and the ftring of the

S 3

other,

other. After this adjustment of the two strings, if they remain untouched till the next day at noon, a meridian line may be obtained at any window in the house which has a fouthern afpect, by fufpending lines as above from the ceiling; that next the window may be fixed, but the other fhould be moveable in a direction nearly east and weft, the weights of these ought also to be immersed in water; then, if two persons attend a little before noon on the next day, one of them at the two first plumb lines which were adjusted to the polar star, and the other at the two plumb lines in the house which are then to be adjusted, each of them holding a fheet of white paper in their hands, to receive the shadow of the two ftrings caft thereon by the fun; the first observer is to give a fignal to the second of the inftant the two shadows on his paper are united in one and the fame line, at which time the fun will be precifely upon the meridian. The other observer in the house is likewise to attend with diligence. and as the fun is coming nearer and nearer to the meridian, he is conftantly to remove his moveable plumb line, and keep the fhadows

dows of his two ftrings always united in one diftinct fhadow, that his observation may be compleat, when his affiftant gives the definitive fignal.

If this be repeated four or five times, a very accurate meridian line may be obtained, and may be drawn on the window, the floor, or a pavement, by their fhadow when united by the fun's rays, and the plumb lines may be occafionally fufpended from two fixed hooks, when you chufe to obferve the paffage of the ftars a-crofs the meridian.

For the use of the curious it will not be improper to observe, that the late Dr. Bradley found that the distance of the star marked  $\alpha$  at the extremity of the tail of the little Bear, from the polar point, was 2 deg. I min. 39 fec. on the first day of January, A. D. 1751, old stile; at the same time its right ascension was 10° 45' 15" equal to 43 min. I fec. of time; and as the right ascension increases 1 min. 16 fec. every ten years, its right ascension may be obtained for any succeeding year; and having the fun's right ascension in time also, subtract the last from the first; by adding 24 hours

to.

to the right afcention of the pole ftar when it is lefs than the fun's, the remainder will be the time of the ftar's coming to the meridian.

Then, as before, hang up two plumb lines, between your eye and the polar ftar.

### PROBLEM LVI.

### Of the equation of time.

306. As time flows with great regularity, it is impossible to measure it accurately, and compare its feveral intervals with each other, but by the motion of some of the heavenly bodies, whose progress is as uniform and regular as itself.

Ancient aftronomers looked upon the fun to be fufficiently regular for this purpofe; but by the accurate obfervations of later aftronomers, it is found that neither the days, nor even the hours, as measured by the fun's apparent motion, are of an equal length on two accounts.

1st, A natural or folar day of 24 hours, is that space of time the sun takes up in passing from any particular meridian to the same again; and one revolution of the earth, with

with respect to a fixed star, is performed in 23 hours, 56 minutes, 4 seconds; therefore the unequal progression of the earth through her elliptical orbit, (as she takes almost eight days more to run through the northern half of the ecliptic, than she does to pass through the southern) is the reason that the length of the day is not exactly equal to the time in which the earth performs its rotation about its axis.

2dly, From the obliquity of the ecliptic to the equator, on which last we measure time; and as equal portions of one do not correspond to equal portions of the other, the apparent motion of the sun would not be uniform; or, in other words, those points of the equator which come to the meridian, with the place of the sun on different days, would not be at equal distances from each other.

This laft is eafily feen upon the globe, by bringing every tenth degree of the ecliptic to the graduated fide of the ftrong brafs meridian, and you will find that each tenth degree on the equator will not come thither with it, but in the following order from  $\gamma$ to  $\mathfrak{D}$ , every tenth degree of the ecliptic comes

comes fooner to the ftrong brass meridian than their corresponding 10ths on the equator; those in the fecond quadrant of the ecliptic, from  $\mathfrak{D}$  to  $\mathfrak{a}$ , come later, from  $\mathfrak{a}$  to  $\sqrt{3}$  fooner, and from  $\sqrt{3}$  to Aries later, whils those at the beginning of each quadrant come to the meridian at the same time; therefore the sun and clock would be equal at these four times, if the sun was not longer in passing through one half of the ecliptic than the other, and the two inequalities joined together, compose that difference which is called the equation of time.

These causes are independent of each other, sometimes they agree, and at other times are contrary to one another.

The time marked out by an uniform motion, is called true time, and that shewn by the fun, is called apparent or solar time, and their difference is the equation of time.

We

We now proceed to fhew how the terrestrial globe will represent the real phœnomena relating to the earth, when actually compared with the refulgent rays emitted from the great sphere of day.

307. The meridians on our new terreftrial globes, being fecondaries to the equator, are alfo hour circles, and are marked as fuch with roman figures under the equator, and at the polar circles. But obferve, there is a difference in the figures placed to the fame hour circle; if it cuts the IIId hour upon the polar circles, it will cut the IXth hour upon the equator, which is fix hours later, and fo of all the reft.

Through the great Pacific fea, and the interfection of Libra, is drawn a broad meridian from pole to pole, it paffes through the XIIth hour upon the equator, and the VIth hour upon each of the polar circles; this hour circle is graduated into degrees and parts, and numbered from the equator towards either pole,

There

There is another broad meridian passing through the Pacific sea, at the IXth hour upon the equator, and the IIId hour upon each polar circle; this contains only one quadrant, or 90 degrees, the numbers annexed to it begin at the northern polar circle, and end at the tropic of Capricorn.

Here we must likewise observe, there are 23 concentric circles drawn upon the terrestrial globe within the northern and southern polar circles, which for the future we shall call polar parallels; they are placed at the distance of one degree from each other, and represent the parallels of the fun's declination, but in a different manner from the 47 parallels between the tropics.

The following problems require the globe to be placed upon a plane that is level, or truly horizontal, which is eafily attained, if the floor, pavement, gravel-walk in the garden, &c. fhould not happen to be horizontal.

A flat feafoned board, or any box which is about two feet broad, or two feet fquare, if the top be perfectly flat, will answer the purpose, the upper surface of either may be set truly horizontal, by the help of a pocket

pocket spirit level, or plumb rule, if you raife or depress this or that fide by a wedge or two, as the spirit level shall direct; if you have a meridian line drawn on the place over which you substitute this horizontal plane, it may be readily transferred from thence to the surface just levelled; this being done, we are prepared for the folution of the following problems.

### PROBLEM LVII.

citobe, at that infant the

To observe the fun's altitude by the terrestrial globe, when he shines bright, or when he can but just be discerned through a cloud.

308. Confider the fhade of extuberancy, which is that caufed by the fphericity of the globe, heretofore called the edge of the earth's enlightened difc, and there reprefented by the broad paper circle, but here realized by the natural light of the fun itfelf.

Elevate the north pole of the globe to 66  $\frac{1}{2}$  degrees, bring that meridian or hour circle,
circle, which paffes through the IXth hour upon the equator, under the graduated fide of the strong brais meridian, the globe being now fet upon the horizontal plane; turn it about thereon, frame and all, that the shadow of the strong brass meridian may fall directly under itfelf, or in other words, that the shade of its graduated face may fall exactly upon the aforefaid hour circle; at that inftant the fhade of extuberancy will touch the true degree of the fun's altitude upon that meridian, which paffes through the IXth hour upon the equator, reckoned from the polar circle, the most elevated part of which will then be in the zenith of the place where this operation is performed, and is the fame whether it should happen to be either in north or fouth latitude.

Thus we may, in an eafy and natural manner, obtain the altitude of the fun, at any time of the day, by the terreftrial globe; for it is very plain, when the fun rifes, he brufhes the zenith and nadir of the globe by his rays; and as he always illuminates half of it, (or a few minutes more, as his globe is confiderably larger than that of

of the earth) therefore when the fun is rifen a degree higher, he must neceffarily illuminate a degree beyond the zenith, and fo on proportionably from time to time.

But as the illuminated part is fomewhat more than half, deduct 13 minutes from the shade of extuberancy, and you have the fun's altitude with tolerable exactness.

If you have any doubt how far the fhade of extuberancy exactly reaches, hold a pin, or your finger, on the globe, between the fun and point in difpute, and where the fhade of either is loft, will be the point fought.

#### When the fun does not fhine bright enough to caft a fhadow.

309. Turn the meridian of the globe toward the fun, as before, or direct it fo that it may lie in the fame plane with it, which may be done if you have but the leaft glimpfe of the fun through a cloud; hold a ftring in both hands, it having first been put between the ftrong brafs meridian and the globe: ftretch it at right angles to the meridian, and apply your face near to the

the globe, moving your eye lower and lower, till you can but juft fee the fun: then bring the ftring held as before to this point upon the globe, that it may juft obfcure the fun from your fight, and the degree on the aforefaid hour circle, which the ftring then lies upon, will be the fun's altitude required, for his rays would flew the fame point if he fhone out bright.

Note. The moon's altitude may be obferved by either of these methods, and the altitude of any star by the last of them.

#### PROBLEM LVIII.

To place the terreftrial globe in the fun's rays, that it may reprefent the natural position of the earth, either by a meridian line, or without it.

310. If you have a meridian line, fet the north and fouth points of the broad paper circle directly over it, the north pole of the globe being elevated to the latitude of the place, and standing upon a level plane, bring the place you are in under the graduated fide

fide of the ftrong brass meridian, then the poles and parallel circles upon the globe will, without fensible error, correspond with those in the heavens, and each point, kingdom, and state, will be turned towards the real one which it represents.

If you have no meridian line, then the day of the month being known, find the fun's declination as before inftructed, which will direct you to the parallel of the day, amongft the polar parallels, reckoned from either pole towards the polar circle; which you are to remember.

Set the globe upon your horizontal plane in the fun-fhine, and put it nearly north and fouth by the mariner's compafs, it being firft elevated to the latitude of the place, and the place itfelf brought under the graduated fide of the ftrong brafs meridian: then move the frame and globe together, till the fhade of extuberancy, or term of illumination, juft touches the polar parallel for the day, and the globe will be fettled as before; and if accurately performed, the variation of the magnetical needle will be fhewn by the degree to which it points in the compafs box.

And

T

PKOBLISS,

And here observe, if the parallel for the day should not happen to fall on any one of those drawn upon the globe, you are to estimate a proportionable part between them, and reckon that, the parallel of the day. If we had drawn more, the globe would have been confused.

The reafon of this operation is, that as the fun illuminates half the globe, the fhade of extuberancy will conftantly be 90 degrees from the point wherein the fun is vertical.

If the fun be in the equator, the fhade and illumination must terminate in the poles of the world; and when he is in any other diurnal parallel, the terms of illumination must fall short of, or go beyond either pole, as many degrees as the parallel which the fun describes that day, is distant from the equator; therefore when the shade of extuberancy touches the polar parallel for the day, the artificial globe will be in the same position, with respect to the sun, as the earth really is, and will be illuminated in the same manner.

ELCORT PAN

#### PROBLEM

PROBLEM LIX.

To find naturally the fun's declination, diurnal parallel, and his place thereon.

311. The globe being fet upon an horizontal plane, and adjusted by a meridian line or otherwife, observe upon which or between which polar parallel the term of illumination falls; its diftance from the pole is the degree of the fun's declination : reckon this diftance from the equator among the larger parallels, and you have the parallel which the fun describes that day ; upon which if you move a card, cut in the form of a double square, until its shadow salls under itfelf, you will obtain the very place upon that parallel over which the fun is vertical at any hour of that day, if you fet the place you are in under the graduated fide of the ftrong brass meridian.

Note, The moon's declination, diurnal parallel and place, may be found in the fame manner. Likewife when the fun does not fhine bright, his declination, &c. may be found by an application in the manner of problem 57.

T<sub>2</sub> PROBLEM

#### PROBLEM LX.

## To find the fun's azimuth naturally.

312. If a great circle at right angles to the horizon paffes through the zenith and nadir, and also through the fun's center, its distance from the meridian in the morning or evening of any day, reckoned upon the degrees on the inner edge of the broad paper circle, will give the azimuth required.

#### METHOD I.

313. Elevate either pole to the position of a parallel sphere, by bringing the north pole in north latitude, and the south pole in south latitude, into the zenith of the broad paper circle, having sirft placed the globe upon your meridian line, or by the other method before prescribed; hold up a plomb line so that it may pass freely near the outward edge of the broad paper circle, and move it so that the shadow of the string may fall upon the elevated pole; then cast your eye immediately to its shadow on the broad paper circle, and the degree it there

there falls upon is the fun's azimuth at that time, which may be reckoned from either the fouth or north points of the horizon.

# METHOD II.

STATIS BORNES

TOTAL

314. If you have only a glimple, or faint fight of the fun, the globe being adjusted as before, stand on the stady fide, and hold the plomb line on that fide also, and move it till it cuts the fun's center, and the elevated pole at the fame time, then cast your eye towards the broad paper circle, and the degree it there cuts is the fun's azimuth, which must be reckoned from the opposite cardinal point.

#### PROBLEM LXI.

To fhew that in fome places of the earth's furface, the fun will be twice on the fame azimuth in the morning, twice on the fame azimuth in the afternoon; or, in other words,

315. When the declination of the fun exceeds the latitude of any place, on either T  $_3$  fide

fide of the equator, the fun will be on the fame azimuth twice in the morning, and twice in the afternoon.

Thus, suppose the globe rectified to the latitude of Antigua, which is in about 17 deg. of north latitude, and the fun to be in the beginning of Cancer, or to have the greatest north declination; fet the quadrant of altitude to the 21st degree north of the east in the horizon, and turn the globe upon its axis, the fun's center will be on that azimuth at 6 h. 30 min. and also at 10 h. 20 min. in the morning. At 8 h. 30 min. the fun will be as it were stationary with respect to its azimuth for some time; as will appear by placing the quadrant of altitude to the 17th degree north of the east in the horizon. If the quadrant be fet to the fame degrees north of the weft, the fun's center will crofs it twice as it approaches the horizon in the afternoon.

This appearance will happen more or lefs to all places fituated in the torrid zone, whenever the fun's declination exceeds their latitude; and from hence we may infer, that the fhadow of a dial, whofe gnomon is erected perpendicular to an horizontal plane,

plane, must necessarily go back feveral degrees on the fame day.

But as this can only happen within the torrid zone, and as Jerufalem lies about 8 degrees to the north of the tropic of Cancer, the retrocession of the Inadow on the dial of Ahaz at Jerusalem, was in the strictest fignification of the word, miraculous.

# PROBLEM LXII.

To observe the hour of the day in the most natural manner, when the terrestrial globe is properly placed in the fun-fhine.

woll-lapping dyeninging the initial for the

316. There are many ways to perform this operation with respect to the hour, three of which are here inferted, being general to all the inhabitants of the earth; a fourth is added peculiar to those of London, which will answer, without fensible error, at any place not exceeding the diftance of 60 miles from this capital.

T 4

and rand water show in mit and numbers into in their a day olarit past and

: Buge:

Lineared in of solar horners, balance - of Ift, By

# 1ft, By a natural stile.

317. Having rectified the globe as before directed, and placed it upon an horizontal plane over your meridian line, or by the other method, hold, a long pin upon the illuminated pole in the direction of the polar axis, and its fhadow will fhew the hour of the day amongst the polar parallels.

The axis of the globe being the common fection of the hour circles, is in the plane of each; and as we fuppofe the globe to be properly adjusted, they will correfpond with those in the heavens; therefore the shade of a pin, which is the axis continued, must fall upon the true hour circle.

#### 2dly, By an artificial stile.

318. Tie a fmall ftring with a noofe round the elevated pole, ftretch its other end beyond the globe, and move it fo that the fhadow of the ftring may fall upon the depressed axis; at that instant its fhadow upon the equator will give the folar hour to a minute.

But

But remember, that either the autumnal or vernal equinoctial colure must first be placed under the graduated fide of the strong brass meridian before you observe the hour, each of these being marked upon the equator with the hour XII.

The firing in this last case being moved into the plane of the fun, corresponds with the true hour circle, and consequently gives the true hour.

## 3dly, Without any stile at all.

319. Every thing being rectified as before, look where the fhade of extuberancy cuts the equator, the colure being under the graduated fide of the ftrong brafs meridian, and you obtain the hour in two places upon the equator, one of them going before, and the other following the fun.

Note. If this fhade be dubious, apply a pin or your finger as before directed.

The reafon is, that the fhade of extuberancy being a great circle, cuts the equator in half, and the fun, in whatfoever parallel of declination he may happen to be,

be, is always in the pole of the shade; confequently the confines of light and shade will shew the true hour of the day.

4thly, Peculiar to the inhabitants of London, and its environs, within the diftance of fixty miles.

320. The globe being every way adjusted as before, and London brought under the graduated fide of the strong brass meridian, hold up a plomb line, fo that its shadow may fall upon the zenith point, (which in this cafe is London itfelf) and the fhadow of the string will cut the parallel of the day upon that point to which the fun is then vertical, and that hour circle upon which this interfection falls, is the hour of the day; and as the meridians are drawn within the tropics at 20 minutes distance from each other, the point cut by the interfection of the ftring upon the parallel of the day, being fo near the equator, may, by a glance of the observer's eye, be referred thereto, and the true time obtained to a tagtine of the owner and the minute. Se INCOLUMN TO multiple of declination be many hore on

Jac.

The

The plomb line thus moved is the azimuth, which by cutting the parallel of the day, gives the fun's place, and confequently the hour circle which interfects it.

From this last operation results a corollary, that gives a fecond way of rectifying the globe to the sun's rays.

If the azimuth and fliade of the illuminated axis agree in the hour when the globe is rectified, then making them thus to agree muft rectify the globe.

#### COROLLARY.

'distant'

17

#### Another method to rectify the globe to the fun's rays.

321. Move the globe till the thadow of the plomb line, which paffes through the zenith, cuts the fame hour on the parallel of the day, that the thade of the pin held in the direction of the axis falls upon, amongst the polar parallels, and the globe is rectified.

The reason is, that the shadow of the axis represents an hour circle; and by its agreement in the same hour, which the shadow of the azimuth string points out, by

by its interfection, on the parallel of the day, it fnews the fun to be in the plane of the faid parallel; which can never happen in the morning on the eaftern fide of the globe, nor in the evening on the western fide of it, but when the globe is rectified.

This rectification of the globe, is only placing it in fuch a manner that the principal great circles, and points, may concur and fall in with those of the heavens.

The many advantages arifing from these capital problems relating to the placing of the globe in the sun's rays, an intelligent reader will easily difcern, and readily extend to his own as well as to the benefit of his pupil.

#### PROBLEM LXIII.

To find when the planet Venus is

a morning or an evening ftar.

322. Rectify the celeftial globe to the latitude and fun's place, art. 189, 190. find the place of Venus by an ephemeris, and fet the artificial moon to that place in the zodiac, which will represent the planet; bring the artificial fun to the eastern edge of

of the horizon; if Venus is then elevated, the will rife before the fun, and be a morning ftar; but if the is depreffed below the horizon, the must then confequently follow the fun, and become an evening ftar.

## PROBLEM LXIV.

To find at what time of the night any planet may be viewed with a reflecting telescope.

323. Rectify the celestial globe to the latitude and sun's place, art. 189, 190. feek the planet's place and latitude in an ephemeris: to which place in the zodiac, fet the artificial moon to represent the planet, and it will shew its place in the heavens: bring the planet's representative to the eastern fide of the horizon, and the horary index will shew the time of its rising; if the artificial fun is then elevated, the planet will not be visible at that time by means of his superior light; therefore turn the globe from east to west until the artificial sun is deprefied below the circle of twilight, art. 93, and 216. where stop the globe, and fcrew

fcrew the nut of the quadrant of altitude in the zenith, art. 192, lay its graduated edge on the center of the planet, and it will fliew in the horizon the azimuth or point of the compass, on which the planet may then be viewed in the heavens; the horary index will at the fame time point out the hour of the night. When the planet comes to the strong brais meridian, the index will shew the time of its passage over that celessial circle; and at the western edge of the horizon, the time of its setting will likewife be obtained.

# USE OF THE GLOBES

In the SOLUTION of

Right Angled Spherical Triangles.

326. A Spherical triangle is formed upon the furface of a globe by the interfection of three great circles.

327. A fpherical angle is the interfection of two great circles that incline to one another; the quantity of any fpherical angle is measured by a third great circle, intercepted between the legs of the angle, at 90 degrees diffance from the interfecting point.

328. A right angled fpherical triangle hath one right angle, the fides about which U are

are called legs, and the fide opposite to it the hypothenuse.

329. An oblique angled fpherical triangle has its angles greater or less than 90 degrees: the folution of fpherical triangles confists in finding the measure of its fides and angles.

330. The fides of any fpherical triangle may be changed into angles, and the angles into fides; if for any one fide, and its oppofite angle, their complement to a femicircle be taken.

#### CASE I.

#### PROBLEM LXVI.

The hypothenuse and one leg being given, to find the reft.

In the right angled spherical triangle ABC, fig. 29. are given

The hypothenuse BC 64 40 The leg AC 42 12 to find the leg BA ACB 331. Fig. 30. elevate the pole P to 42° 12', the quantity of the given leg AC, and number the same quantity on the strong brais

brass meridian from  $\mathcal{E}$ , the equator to Z, the zenith; there fix the quadrant of altitude. Bring that meridian which passes through London under the brass meridian, and count  $64^{\circ}$  40', the measure of the hypothenus, on the quadrant downwards from Z to G, and move it till the point G intersects the equator, and the triangle ZG  $\mathcal{E}$ will be formed.

The fide ÆZ represents the given fide A C, the hypothenuse B C is represented by the arch Z G, the required fide A B is represented by G Æ an arch of the equator, its measure  $54^{\circ}$  43', between Æ and G is the quantity fought; the angle A C B, is represented by the angle G Z Æ, and its measure is found on the arch A O of the horizon equal to  $64^{\circ}$  35'.

332. To find the other angle A B C, having obtained the measure of the fide B A,  $54^{\circ}$  43', elevate the pole P agreeable thereto, and reckon the fame from Æ to Z; there fix the quadrant of altitude; number the other leg A C,  $42^{\circ}$  12' from Æ to G on the equator (the meridian paffing through London remaining as before) and to that point bring the quadrant of altitude; then

the arch AO, on the horizon, will contain  $48^{\circ}$  00', the measure of the angle EZG, equal to ABC, the angle fought.

#### CASE II.

#### PROBLEM LXVII.

The hypothenuse and an angle being given, to find the reft.

In the right angled triangle ABC, fig. 29, are given

The hypothenule BC  $64_{40}$ The angle ACB  $64_{35}$  to find the legs ABC AB AB AB AB

333. Fig. 33. place P p the poles of the globe in the horizon HO, and fix the quadrant of altitude to Z the zenith; number  $64^{\circ}$  35', the measure of the given angle, upon the horizon from Æ to F; move the quadrant to the point F, and thereon count  $64^{\circ}$  40', the quantity of the hypothenuse from Z downwards to G, to which point bring that graduated meridian which passes through Libra  $\approx$ , and the triangle GZ  $\approx$  will be formed.

ZG

ZG an arch of the quadrant of altitude represents the hypothenuse;  $Z \cong$  an arch of the equator represents the required side AC equal to  $42^\circ$  12', and G  $\cong$  an arch of the meridian;  $P \cong p$  equal to  $54^\circ$  43', is the measure of the other required side AB.

Now having found the fide A B, adjacent to the required angle A B C, its measure may be found by art. 332.

#### CASE III.

PROBLEM LXVIII.

### A leg and its adjacent angle being given, to find the reft.

In the right angled triangle A B C, fig. 29. are given

The leg BA  $54^{\circ}$   $43^{\circ}$  to find The angle ABC  $48^{\circ}$   $00^{\circ}$  to find the leg AC. ACB. ACB. ACB. BC.

334. Fig. 30. elevate the pole P, to 54° 43', the quantity of the given leg BA; count the fame from Æ to Z, and fix the quadrant at Z; bring that meridian which paffes through London under the ftrong U 3 brafs

brafs meridian, and reckon the given angle  $48^{\circ}$  oo', from O to A, on the horizon; bring the quadrant to A, and the triangle Z G Æ will be formed.

We have the measure of the required fide CA upon Æ G an arch of the equator, equal to  $42^{\circ}$  12', and the hypothenuse BC, upon GZ, an arch of the quadrant, equal to  $64^{\circ}$  40', the angle ACB may be found by art. 332.

# CASE IV.

# PROBLEM LXIX.

# Both legs given, to find the reft.

In the right angle triangle A B C, fig. 29, are given

The legs  $\begin{cases} AB & 54 & 43 \\ AC & 42 & 12 \end{cases}$  to find  $\begin{cases} the hyp. CB \\ the angles \end{cases} \begin{cases} ACB \\ ABC \end{cases}$ 

335. Fig. 25. elevate the globe to the quantity of either given leg as AC,  $42^{\circ}$  12', number the fame from Æ to Z, and fix the quadrant at Z, fet the meridian which passes through London under the strong brass meridian, and count the other given leg AB,  $54^{\circ}$ 

54° 43' upon the equator from Æ to G, bring the quadrant to G, and the triangle ZGÆ will be formed.

The arch ZG on the quadrant of altitude  $64^{\circ}$  40' is equal to BC the hypothenule, the arch OA,  $64^{\circ}$  35' on the horizon, is the measure of the angle GZÆ, equal to the required angle ABC. The other angle may be found by art. 332.

#### CASE V.

PROBLEM LXX.

# Both angles given, to find the three fides.

In the right angled triangle ABC, fig. 29. are given

The angles  $\begin{cases} ACB & 64 & 35 \\ ABC & 48 & 00 \end{cases}$  to find  $\begin{cases} the hyp. BC \\ AC \\ the fides \end{cases} \begin{cases} ACB \\ AC \\ BC \end{cases}$ 

336. In this fifth cafe, we must have recourse to art. 330, and then we shall have an oblique angled spherical triangle abc, fig. 31. whose fide ab is equal to the angle ACB of the given triangle; the fide bc, equal to the angle ABC; and the fide ac,  $U_4$  equal

#### .296 . Description and Use of the

equal to the complement of the right angle to 180 degrees, which must therefore neceffarily be 90 degrees.

337. Fig. 30. number  $48^{\circ}$  oo' the fide bc of this fecond triangle, from P, the pole of the globe to Z, and there fix the quadrant of altitude; then bring the point Z into the zenith, art. 192. and count 90° oo' the quantity of the fide a c, from P the pole to G, upon that meridian which paffes through  $\approx$ ; number the fide a b,  $64^{\circ}$  35' upon the quadrant of altitude downwards from Z to G, then move the globe and the quadrant, until these quantities meet in one point at G, and the triangle PZG will be formed.

The arch  $\mathcal{E}$  G, on the equator, will give the measure of the angle  $\mathcal{E}$  PG 54° 43', equal to the required fide AB; and the arch AO, in the horizon, that of the angle GZ $\mathcal{E}$  64° 40', which is the complement of the angle PZG to 180 degrees, and is equal to the hypothenuse BC: thus having obtained the measures of two of the required fides, we have sufficient data to find the third fide AC, either by the first or second of the preceeding cases, art. 331, 333.

a more the point a

344. This cafe may be refolved as the fifth cafe of right angled fpherical triangles art. 336. by converting the angles into fides, then finding the angles as in the last problem,

blem, where the angles in the converted triangle will be the fides required in this.

Having thewn how to folve all the cafes in right and oblique angled thereical triangles, we proceed to the the extensive use of the globes in the folution of a few of the principal aftronomical problems, according to Dr. Flamfted's doctrine of the there; and as we do not know the have ever yet been applied to the globes, hope the reader will think them both entertaining and useful.

IQ AN Inon

The

The Ufe of the Globes in the Solution of fpherical Problems.

#### PROBLEM LXXVII.

GIVEN, the fun's place in the ecliptic in & 12° 15'. The inclination of the planes of the equator and ecliptic, 23° 29'.
TO FIND the fun's right afcention from the first point of Aries, the fun's distance from the north pole of the world, and the angle, which the meridian, passing through the fun at that place, makes with the ecliptic.

345. Fig. 34. The circular fpace marked  $\mathfrak{S}, \mathfrak{A}, \mathfrak{V}, \mathfrak{T}$ , reprefents the ccliptic, e its pole, P the north pole of the world, elevated  $66\frac{1}{2}$  degrees above the first point of  $\mathfrak{S}$ . The eye is supposed to be placed directly. X over
over the point e, when the reader compares this figure with the globe.

Make a mark  $\bigcirc$ , at  $12^{\circ} 15'$  in Taurus, to represent the fun's place in the ecliptic, and turn the globe till that meridian which passes through  $\simeq$  intersects the point  $\bigcirc$ ; it will then represent the fun's meridian at that time.

The globe being thus rectified, we have between the fun's proper meridian  $P \odot$ , and the folftitial colure  $\mathfrak{D} P$  vs, here reprefented by the firong brais meridian, with the arch  $\mathfrak{D} \mathfrak{D}$ , a fpherical triangle  $\mathfrak{D} \mathfrak{D} P$ , right angled at  $\mathfrak{D}$ , in which we have the following data. See fig. 34.

- 5 0 47° 45', the complement of Υ 0, which is the fun's diffance from the first point of Aries.
- 5 P 66° 31, the complement of P e, 23° 29', the diffance of the poles of the equator and ecliptic.
- To find the angle S P O, the complement of O P Υ, the fun's right ascension from the first point of Aries, art. 202.
- The fide P  $\odot$ , the fun's diffance from the north pole of the world. And

134-7-

The

THE SURGENTY

The angle 5 0 P, which is the angle that the meridian passing by the fun makes with the ecliptic.

We obtain the measure of the first, by numbering the degrees upon the equator, between the ftrong brafs meridian, and that which passes through a, which are equal to 50° 12', its complement; 39° 48' is the fun's right afcenfion, which is that angle at the pole formed by the proper meridian  $\odot$  P with the meridian  $\Upsilon$  P.

Note, This arch of the equator could not be represented in fig. 34. it being under the broad paper circle; but the reader will fee it plainly when the globe is thus rectified.

The quantity of the fecond postulatum, which is the fun's diftance from the nearest pole, is found by infpection, 74° 27' upon the arch P o of that meridian paffing thro' a, its complement P i, equal to 15° 33', is the diftance of the north pole from the edge of the illuminated difc, reprefented upon the globe, as in fig. 34. by the femicircle feg, the black line fe being the quadrant of altitude, and the other dotted X 2 half

half e g being fupposed; or, if the reader pleases, he may represent it with a string. This complement P i is, by Mr. Flamsted, called the reflection, and is ever equal to the fun's declination.

Laftly, the measure of the angle  $\mathfrak{B} \mathfrak{O} P$ , is obtained by fcrewing the quadrant to e the pole and zenith point of the ecliptic, and counting 90 degrees from  $\mathfrak{O}$  to f; thither bring its lower end, then will the arch  $\mathfrak{O}$ i be a quadrant also; and the quantity 72° 10', counted from f to i, upon the quadrant of altitude, is the measure of the required angle  $\mathfrak{D} \mathfrak{O} P$ , formed by the meridian i P  $\mathfrak{O}$ with the ecliptic  $\mathfrak{O} \mathfrak{D} \mathfrak{A}$ .

### PROBLEM

### PROBLEM LXXVIII.

Given, the fun's place in the ecliptic  $\heartsuit 12^{\circ} 15'$ , the reflection or declination  $15^{\circ} 33'$ , and latitude of the place, fuppofe London,  $51^{\circ} 32'$ .

To find the time of the fun's rifing and fetting; the length of the day and night; the amplitude of the rifing-fun from the eaft, and of the fetting-fun from the weft; and that of the path of our vertex in the edge of the illuminated difc.

346. Fig. 35. elevate P, the pole of the globe, to  $15^{\circ}$  33', the fun's declination, above the plane of Bd G i, the circle of illumination: count the fame quantity from Æ the equator to  $\mathfrak{S}$ , at which point fix the quadrant of altitude; this point will reprefent the fun's place; make a mark upon the globe on that meridian which paffes thro' X 3  $\Rightarrow$  at

= at 51° 32' the given latitude; this will express a point in the path of the vertex of London: bring this point to the edge of the difc at B, and fet the lower end of the quadrant thereto: B is that point in the difc from which the fun is feen to rife, or where the vertex of London in its diurnal motion from west to east, passes out of the obscure into the enlightened part of the difc; i P d is the fun's proper meridian, which is reprefented in this by the strong brass meridian. O is the place at which the vertex of London arrives at noon, being 51° 32' from Æ the equator to O, and G the place in the difc, from which the fun is feen to fet, or where the vertex passes out of the illuminated into the obscure part of the disc. BOG is the diurnal, and G---B, on the other fide of the difc, (not here represented, but to be ieen upon the globe) is the nocturnal part of the path of London.

If you bring the mark on that meridian which paffes through  $\simeq$  to the point G, and the quadrant of altitude to the fame point, it will be plain that we shall have two triangles formed on each fide of i P $\odot$ , the fun's proper meridian, viz.  $\odot$  PB, BiP, on

on the oriental or afcending fide, and mPG. 1PG, on the occidental or defcending tide.

In either of these four triangles there are fufficient data to find what is required in this problem. In the triangles OPB, OPG, are given, @ P in both, the fun's diftance · from the pole, PB, equal to PG, the diftance of the vertex from the pole, which is always equal to the complement of the latitude, with the fides OB, OG, each equal to go degrees.

To find the angle PBO, or PGO, the fun's amplitude from the north, when rifing or fetting; and the angle OPB, or OPG, the time before noon. But as the two laft mentioned angles are obtufe, we chufe to refolve this problem by one of the two leffer triangles PBi, PGi, cach of them being right angled at i, in which are given, P i, the reflection, 15° 33', equal to the declination, BP, equal to PG, 38° 28', the diftance of the pole from the vertex.

To find the angle PBi, or PGi, the complement of  $\odot$  Bi, or  $\odot$  Gi, the fun's amplitude at rifing or fetting from the east or west, and the angle i P B, equal to the angle i PG, which are formed between the fun's X 4

fun's proper meridian, and that which pafies through the vertex at fun-rifing or fetting: this changed into time, expresses the time from midnight, of fun rifing and fetting. The fide B i is called the amplitude of the path of London in the edge of the difc, and these are obtained from the globe as follows.

The measure of the angle B P i is obtained by infpection, reckoning from  $\Rightarrow$  upon the equator to the ftrong brass meridian, which is 96° 31': if reduced to time, it is 4 h. 38 m. in the morning, at which time the fun rifes at London, when he is in  $\bigotimes$ 12° 15', and confequently fets at 7h. 22m. afternoon. See art. 249.

The quantity  $35^{\circ}$  38' of the required fide B i, is obtained by infpection between B and i, upon the edge of the difc.

The measure of the angle P B i may be attained as follows: every thing elfe remaining as before, bring the graduated edge of the moveable meridian to the first point of  $\gamma$  on the ecliptic; then count the complement 54° 22' of the fide B i, from i to x, where make a mark; and count the complement of B P, 51° 32' from P to y, upon the

the moveable meridian, where make another mark; remove the quadrant of altitude, and apply it between these two marks, and the quantity 25° 31' is the measure of the angle P B i, art. 327. This is the fun's amplitude from the east, or N. E. 3° 1' easterly.

#### PROBLEM LXXIX.

- Given, the latitude of the place 51° 32', or rather its complement 38° 28', which is the diftance of the path of the vertex from the pole, and the fun's diftance from the pole, 74° 27', which is the complement of his declination 15° 33'.
- To find the fun's diftance from the vertex at the hour of fix, and his amplitude at that time.

347. Fig. 35. Elevate P, the pole of the globe, to 15° 53', the declination; bring the moveable meridian to that which paffes through London; flide the artificial horizon to

to  $51^{\circ}$  32', the latitude of the place, and turn the globe till the fixth hour upon the equator comes under the graduated fide of the ftrong brafs meridian; then the moveable meridian, together with that which paffes thro'  $\Rightarrow$ , will reprefent the fix o'clock hour-circle FKPAg; fix the quadrant of ' altitude to  $15^{\circ}$  33', at the point o, counted from Æ the equator; turn the quadrant to the point K, which reprefents the center of the artificial horizon, and the proper triangles will be formed.

In the right angled fpherical triangles  $AP \odot$ ,  $KP \odot$ , right angled at P, are given PK, equal to PA,  $38^{\circ} 28'$ , the diffance of the vertex from the pole,  $\odot P$ , the path's diffance from the pole  $74^{\circ} 27'$ . To find  $\odot K$ , or  $\odot A$ , the fun's diffance from the vertex at the hour of fix, and either of the angles,  $\odot AP$ , or  $\odot KP$ , the fun's azimuth from the north at the fame time.

It is plain that Po, being the fun's proper meridian, FPg at right angles to it, must be the hour-circle of fix in the morning and evening, and that the fun rifes, when the vertex B comes in the western edge of the fun's enlightened dife. Therefore it

it must be at K, at fix o'clock in the morning; at noon the vertex will be at O, upon OP, the fun's proper meridian; and at fix in the evening it will be at A, upon the fix o'clock hour-circle again; and when the vertex arrives at G, upon the eastern edge of the dife, the fun will be feen to fet westward of the vertex.

The required fide  $\odot K$ , which is the fun's distance from the vertex, is found by counting the quantity 77° 53' upon the quadrant, from O to K; and the angle O KP, 80° 111: the fun's azimuth from the north may be measured by producing the fide KO, to go degrees from K to m, (art. 327.) the fide KP being already produced on the other fide of the strong brass meridian, K P is known to be 28° 28'; therefore count its complement 51° 32', from P to n, upon that meridian which paffes through and, and there make a mark; now remove the quadrant of altitude to cut the opposite point of the horizon to that at which it flood before, and count thereon from @ downwards 12° 07' to m, where make another mark; then an arch of a great circle applied to

Real I

to these two marks will give 80° 11', the sun's azimuth from the north.

Note, A flexible femicircle of polition, if applied with the quadrant of altitude, will be found uleful in this and many other cafes.

## PROBLEM LXXX.

To find the fun's diftance from the vertex when due east or west, and the hour, or time from noon, when he shall be in either of these points.

348. Fig. 35. the north pole of the globe being elevated to the fun's declination, as in the last problem, and the quadrant fixed at  $\bigcirc$  as before, the moveable meridian placed on that of London, and the center of the artificial horizon set to the fame point; turn the globe so that the graduated edge of the quadrant may lie upon the east and west points of the artificial horizon, and the triangle  $\bigcirc$  K P will be formed; in which is given  $\bigcirc$  P, the fun's distance from the pole 74° 27'; PK the distance of the path from the pole, 38° 21';  $\bigcirc$ K, the fun's

fun's diftance from the vertex, when due east and west, may be found by inspection, counting from  $\odot$  to K upon the quadrant, 70° o': the measure of the angle  $\odot$  P K is also obtained upon the equator, counting from that point where it is crossed by the quadrant of altitude, to its intersection with the graduated fide of the strong brass meridian, 77° 53', in time 5 h. 9 m. from noon, which is 51 min. past 6 in the morning; or at 9 min. past 5 in the asternoon, when the fun is due east or west.

The fun's diffance  $70^{\circ}$  o' from the vertex as found above, when due eaft or weft fubtracted from 90 degrees, leaves 20 deg.' which is its altitude above the horizon at either of these times, for  $\circ v$ ,  $\circ w$  are quadrants, from which if we take  $\circ K$  in the first, or  $\circ A$  in the second, it is K v, in one and A w in the other, equal to the fun's height.

and a second sec

PROBLEM

### PROBLEM LXXXI.

Given the hour from noon, viz. 8 in the morning, which is 4 hours from noon, and the fun's diftance from the pole, 74° 27'.

To find his distance from the vertex,

349. Fig. 35. elevate P the pole of the globe to the fun's declination, 15° 33' fet the moveable meridian to the vertex of London, and flide the center of the artificial horizon to that point at K, and turn the globe, until the eighth hour-circle marked upon the equator comes under the graduated fide of the strong brass meridian; the quadrant of altitude being fixed at the point @ as before, turn it to the point K, and the triangle OPK will be formed; in which is given the angle K P O, four hours from noon, PK, 38° 28' the distance of the path from the pole; • K the fun's diftance from the vertex will then be found, by infpection on the quadrant, counting from Q to K 59° 20'.

STATE TO A

PROBLEM

#### PROBLEM LXXXII.

Given the fun's diftance from the pole 74° 27', the latitude of the place 51° 32', and the fun's diftance from the vertex by obfervation, 46° 11'.

To find the time of the day when that observation was made, and the azimuth upon which the fun was at that time.

350. Fig. 35. elevate P, the pole of the globe to 15° 33' the complement of the fun's diftance from the pole; bring the moveable meridian to the vertex of London, and flide the center of the artificial horizon to that point: then fcrew the quadrant to  $\Theta$  the zenith of the illuminated difk, and bring its graduated edge to London; and move the globe and quadrant, that the vertex may cut the quadrant at 46° 11', the obferved diftance counted from  $\Theta$  to K; and an oblique angled triangle  $\odot$  K P will be formed upon the globe, in which we have three fides

fides given,  $\bigcirc P$ , 74° 27' the fun's diftance from the pole,  $\bigcirc K$  his observed diftance from the vertex 46° 11' in the morning, and KP 38° 28' the diftance of the pole from the vertex : to find the angle K P  $\bigcirc$ , count the quantity contained upon the equator, between the moveable and strong brass meridians, which will be found 36° 23', or 2 h. 25 m. in time from noon, which is 35 minutes past 9 o'clock in the morning.

The angle PK  $\odot$  may be meafured by producing the arches which include the angle to the diftance of 90 deg. from the angular point as in art. 332. or by art. 339. and it will be found 127° 40', or 11 points of the compass from the north, reckoned round by the east, or SEbE, 3° 35' foutherly.

If the observation had been made in the afternoon, at the same height or distance from the vertex, the answers would have been the same, but in a contrary direction.

By this problem we may regulate our clocks at any time of the day, without ftaying till the fun comes to the meridian; if the fun's altitude be taken by a large quadrant,

drant, and you note the time by the clock when the obfervation was taken, and the true time anfwering thereto be found as above, or by calculation, the difference between this and the time pointed out by the clock at the inftant of obfervation will fhew how much the clock is before or behind the folar apparent time.

#### PROBLEM LXXXIII.

- Given, the latitude of the place 51° 32', the fun's place  $\heartsuit 12^{\circ} 15'$ , the fun's right afcenfion, 39° 48', at one o'clock afternoon, being the time when an obfervation was made:
- To find, what point of the ecliptic culminates upon the meridian, which is the higheft point of it, or the 90th degree from the points wherein it interfects the horizon, and confequently those points themselves; the distance of the nonagefimal and mid-heaven points Y from

from the vertex; and the angle made by the vertical circle paffing through the fun at that time with the ecliptic.

251. Fig. 24. elevate P the pole of the globe to  $66\frac{1}{2}$  degrees, count the fame quantity from Æ the equator to e, there fix the quadrant of altitude; this point e, will then be the pole of the broad paper circle marked Y 5 = VS, which now reprefents the ecliptic, in which at @ put a mark, at O 12° 15' for the place of the fun; bring the graduated edge of the moveable meridian first to the vertex of the given place, in this example London, and bring the center of the artificial horizon thereto; next fet it to the point marked O, and the horary index to that XIIth hour upon the equator which is most elevated, and turn the globe until the given time one hour from noon comes under the horary index. Then fet the graduated edge of the quadrant of altitude to the vertex at E, and the globe will be rectified for a folution of this problem, in which we have two spherical triangles, P 5 D, and cPE.

E, is

E, is that point in the path on which the vertex is at one o'clock afternoon, D, that point of the ecliptic which then culminates upon the meridian  $E \oplus \mathfrak{S}$ , the angle made by  $E \oplus$  the vertical circle then paffing thro' the fun with the ecliptic; the point T in the ecliptic, which is cut by the quadrant of altitude paffing through E, is evidently the nearest point to the vertex, or the highest or nonagesimal point of it. E T is the distance of the point T from the vertex E, and E D the distance of D from the vertex, which is the point then culminating upon the meridian.

In the triangle  $D \mathfrak{S} P$ , is given the angle  $\mathfrak{S} P D$ , the complement of  $\Upsilon P D$ , which is the right afcention of the mid-heaven, the fun's given right afcention  $39^{\circ} 43'$ , agreeable to the fun's place  $\mathfrak{S} 12^{\circ} 15'$ , at noon, to which the addition of  $15^{\circ}$  for one hour after noon, as we did above in rectifying the globe, makes the angle  $\Upsilon P D$   $54^{\circ} 48'$  the prefent right afcention of the mid-heaven and PED the meridian at that time;  $P \mathfrak{S} 66^{\circ} 31'$ , and the angle at  $\mathfrak{S}$ right.

I. To

Y 2

I. To find  $\mathfrak{D}$  D, the complement of  $\mathfrak{T}$  D, the longitude of PD the mid-heaven from the first point of  $\mathfrak{T}$ , which is obtained on the ecliptic here represented by the broad paper circle between points  $\mathfrak{D}$  and D,  $32^\circ 54'$ , or between  $\mathfrak{T}$  and D,  $57^\circ 6'$ , the longitude itself, which is  $27 \deg .6 \min$ . in Taurus. D is that point of the ecliptic which culminates upon the meridian at that time, whence we may readily find what points of the ecliptic rife and fet at that time.

The quantity 70° 27' contained between P the pole of the globe and D upon the moveable meridian, is the diftance of D the mid-heaven point from the pole; if we deduct PE 38.28, or count the quantity between D and E, we shall have  $31^{\circ}$  59', the diftance of the point D in the ecliptic which now culminates on the meridian from the vertex E, its complement to 90 degrees being  $58^{\circ}$  1' is the height of the ecliptic at this time, or the inclination of the ecliptic to the horizon of the place.

II. To find 5 T, the complement of  $\Upsilon$  T, which is the longitude of the nonagefimal, Celestial and Terrestrial Globes. 325 gefimal, and TE its diftance from the vertex.

In the oblique angled spherical triangle P e E, are given  $P e 23^{\circ} 29'$ , the distance of the poles of the equator and ecliptic, P E,  $38^{\circ} 28'$  the co-latitude with the included angle  $e P E 144^{\circ} 48'$ , the complement of  $35^{\circ} 12'$  the distance of the mid-heaven from the first point of  $\mathfrak{D}$  to 180 degrees. The measure of this angle is obtained upon the equator between the strong brass, and the moveable meridians.

To find the angle PeE, as it is included between 55 e, the ftrong brass meridian, and eT the quadrant; we have its measure 24° 44' upon the arch 5 T of the ecliptic, its complement 65° 16' is Y T, the longitude of the nonagefimal from the first point of Aries, or 11 5° 16' its distance E T from the vertex E, is gained on the quadrant of altitude 31° 2', the complement of which  $58^{\circ}$  58' is the altitude of the ecliptic above the horizon at this time; or it is the angle which the planes of the ecliptic and horizon make with each other; as T is the highest point of the ecliptic at this time, and its longitude in I 5° 16', three figns or 90 Y 3 degrees , 0.1

degrees counted on the broad paper circle from T towards x will give  $\frac{11}{5} \circ 16^{1}$  for that point of the ecliptic which is then rifing, and the fame quantity counted from T towards y will fall upon  $\times 5^{\circ} 16^{1}$  which point is then fetting.

III. To find the angle  $E \odot T$  being that which a vertical circle  $E \odot$  passing through the fun at that time makes with the ecliptic; this is called the parallactic angle.

To represent this angle upon the globe it is neceffary to have a flexible flip of brafs, or a flip of parchment about the breadth of the quadrant of altitude, with the divisions inscribed on it with a pen; if this flip be applied to the point  $\odot$  and its graduated edge laid over the vertex E, and extended to the quadrant of altitude first removed to x 90 degrees from  $\odot$  it will interfect the quadrant at w, the quantity upon the quadrant, from x to w, will be 56° 29', the measure of the parallactic angle E  $\odot$  T. The result of this problem is as follows:

That point of the ecliptic which culmiminates on the meridian is in  $\heartsuit 27^\circ 6'$  its diftance from the vertex 31° 59', the highest or nonagefimal point of the ecliptic,  $\pi$  $5^\circ 16'$ ,

5° 16', its diffance from the vertex  $31^{\circ}$  2', the rifing point of the ecliptic  $\mathbb{W}$  5° 16', its fetting point  $\times$  5° 16', the diffance of the nonagefimal from the mid-heaven 8° 10', and the parallactic angle at this time 56° 59'.

#### PROBLEM LXXXIV.

orli we inchitte

Given, the latitude of the place, right afcention and declination of any point of the ecliptic, or of a fixed flar:

To find its rifing or fetting amplitude, its ascensional difference, and thence its oblique ascension.

352. Fig. 36. elevate P, the pole of the globe to 51° 32', the latitude of London; then the diurnal parallel of the first point of Cancer will be represented by  $\mathfrak{S}$  F, the tropic of that name, marked  $\mathfrak{S}$  e F, in fig. 36, bring the first point of  $\mathfrak{S}$ on the ecliptic line to the graduated edge of the strong brass meridian, and e will be the point where it rifes; to this point bring the graduated edge of the moveable meridian, Y 4 represented

represented in the figure by P e g p, then a e, upon the horizon at HO, or the angle a Z e, from the angular point Z m, the zenith will be its rifing amplitude, from the east at Aries, towards the north point of the horizon at o, and a g, determined by the moveable meridian, which now represents a circle of right ascension passing through the points e and g, and the horizon its afcensional difference, which subtracted from its right, leaves its oblique ascension.

The ascensional difference is the difference between that point of the equator, which culminates upon the meridian, with the first point of Cancer, and that other point of the equator which rifes with it above the horizon; it is here subtracted, to find the oblique ascension; because that point of the equator which rifes with the first point of Cancer, comes to the horizon before the point of its right ascension, or that point with which it culminates upon the meridian.

In the triangle age, we have ge, the northern declination of the point e, in the diurnal parallel of the first point of Cancer, equal to 23° 29', the angle gae, which is the inclination of the planes of ÆQ the equator,

equator, and HO the horizon, with the angle at g right. Whence upon the horizon we obtain between a and e,  $39^{\circ}$  50', the rifing amplitude of the first point of  $\mathfrak{S}$ , which is N E b E, and 5° 20' more. Upon the equator, from a to g, we find  $33^{\circ}$ 9', the ascensional difference of the first point of Cancer: which subtracted from 90 deg. the right ascension of that point, leaves  $56^{\circ}$  51', its oblique ascension.

Every thing elfe upon the globe remaining the fame, if we bring the moveable meridian to the point n, where the tropic of Capricorn interfects the horizon, we shall have another triangle ab n, equal to the former, wherein the first point of Capricorn has the fame amplitude 23° 29' from a, in the east, to n, towards H, the south part of the horizon, that the former triangle had towards the north; and this added to the right ascension of the first point of Capricorn, 270' 00', gives its oblique ascention 303° 09', because that point of the equator which rifes with the first point of Capricorn comes to the horizon after the point of its right ascension, or that with which it culminates upon the meridian.

353. Note,

353. Note, Every ftar which rifes with any point of the ecliptic has the fame oblique alcention with that point.

The ftar marked v, in the leg of the conftellation Bootes, of the fourth magnitude, which is represented in fig. 36. at the point \*, having its north declination  $f * 17^{\circ} 21'_{4}$ its ascensional difference a f, rifes above the horizon with the same point of the equator with which e, in the diurnal parallel of the first point of Cancer, rifes. So that having its right ascension  $204^{\circ}$ , and declination  $17^{\circ} 21'$ , its ascensional difference and oblique ascension may be found in the triangle a f \*, in the same manner in which the former were found in the triangle a g c.

As the afcentional difference is fubtracted from the right afcention to find the oblique afcention, if it be added to the right afcention it will give the oblique defcention. For that point of the equator which fets with the diurnal parallel of the first point of Cancer, comes to the horizon before the point of its right afcention, or that with which it culminates upon the meridian. Hence we have another method of finding the

the length of the day at London, or elfewhere, when the fun is in the first point of Cancer, or any other parallel of his declination, viz.

354. Subtract the fun's alcentional difference in time from fix in the morning, the refidue is the time of his tifing; add it to fix in the evening, and it gives the time of his fetting; then doubling the first you obtain the length of the night, and the double of the last will be the length of the day. And after this manner all these particulars may be found to every intermediate point of the celiptic in all datitudes.

As the rifing and fetting of fome of the principal fixed ftars are mentioned by ancient writers, as criteria, by which to judge of the commencement of feafons, and the beginning of times fet apart for religion, hufbandry, politicks, &c. we have judged it neceffary to add the following problems, as a farther elucidation of the two former, art. 302 and 303.

a will be that point if alls cellpaid in which

PROBLEM

#### PROBLEM LXXXV.

the tunoihould the reported whether and

Given, the latitude of the place, the points of the ecliptic with which a ftar rifes or fets, and the altitude of the nonagefimal, when those points are upon the horizon :

To find in what points of the ecliptic the fun must be to make the star when rising or setting appear just free from the solar rays; and thence the times of its heliacal rising and setting.

355. Fig. 36. Elevate P, the pole of the globe, to the latitude of the place, and fix the quadrant of altitude in the zenith at Z, and HO will reprefent the horizon. Turn the globe until the given ftar just appears at \* in the edge of the horizon, and a will be that point of the ecliptic in which the fun must be when the ftar rifes and fets with it: Let us suppose the ftar at \* to be of the first magnitude, which requires that the

the fun fhould be depressed 12 degrees below the horizon, that the star may appear free from the solar rays: having noted the point a, on the ecliptic, move the quadrant until the 12th degree below the horizon intersects the ecliptic at s, then Z s will represent a vertical circle, in which the sun at s is depressed 12 degrees.

So in the triangle a C S, right angled at C, we have the fides C S, 12 degrees, the requifite depression of the fun below the horizon, to free the star from his rays, or that point of the ecliptic at S, to make the star at \* first heliacally visible when it rises, or from which we may see upon the other fide of the globe when it fets heliacally.

The angle SaC is the altitude of the nonagefimal, or inclination of the planes of the ecliptic and horizon; and the angle at C right, being formed by the interfection of a vertical circle with the horizon: the measure of the angle SaC, is obtained by inspection on the brass meridian from O to vs, the point in which the tropic of Capricorn cuts that circle; the side a S, being an arch of the ecliptic, through which the sum and the time the star at v rifes with

with him to-its heliacal rifing, or an arch of the fame quantity on the other fide of the globe, through which the fun must have passed from the time when the far fet heliacally, to its fetting with the fun, which, as in the former case, added to the point of the ecliptic, in which the fun is when the star rifes with him, gives the point he is in at its heliacal rifing; and in the latter case subtracted from that point of the ecliptic the fun is in when the star fets with him, leaves the point he is in at the same star's heliacal setting.

Thus having found the points of the ecliptic in which the fun must be when any ftar rifes or fets heliacally, against those points in the kalendar, on the horizon, you obtain the month and day.

As the diffances of the fixed ftars from one another have been found the fame in all ages, it is probable they have no real motion of preceffion, but only an apparent one, caufed by the retroceffion of the equinoctial points, which are found to recede from their ancient ftations at the rate of 50 feconds every year; this alters their longitude, but their latitude does not vary: hence their

B PREASTRONG

The regular change in the precession of the fixed stars, or rather the constant retrogression of the equinoctial points, seems to cause an irregular variation in their right ascensions and declinations, more or less, according to their distances from the pole of the ecliptic. Whence it may not be improper to shew how these may be found, as the cosmical, achronical, and heliacal risings and settings of the fixed stars, found by the preceding problems, have respect only to the present age : and the following problem, with which I shall conclude this treatise, will shew the reader how to determine the ancient place of any star agreeable

to

to the time of ancient authors, if their authority may be depended on.

### PROBLEM LXXXVI.

Given, the latitude and ancient longitude of a fixed ftar :

### To find its right afcenfion and declination.

Elevate the celeftial globe to  $66\frac{1}{2}$  degrees, bring the pole of the ecliptic into the zenith, and there fix the quadrant of altitude; apply its graduated edge to the given ftar, and it will cut its prefent longitude, either on the ecliptic or broad paper circle, which in this polition of the globe coincide with each other : make a mark on the quadrant. at the latitude of the given star, and remove it to its ancient longitude, as found above ; then bring the graduated edge of the moveable meridian to the mark just made upon the quadrant of altitude, and fet the center : of the artificial fun to that point which will then represent the ancient place of the given ftar. That point of the moveable meridian, is upon which the center of the artificial fun

was
was placed, is its ancient declination; and that point of the equator, cut by its graduated edge, is its ancient right ascension.

The globe being thus rectified to the place and precefiion of any particular flar, as given us by ancient authors, the times of the year when fuch flar role or fet, either cofmically, achronically, or heliacally, may be thus obtained by the preceding problems, agreeable to the period of the author under confideration.

## CATALOGUE

OF

A

Mathematical, Philosophical,

Optical INSTRUMENTS.

AND

MADE and SOLD by

GEORGE ADAMS,

Mathematical Inftrument-Maker to the KING,

At his Shop the Sign of Tycho BRAHE'S Head, (N<sup>o</sup>. 60) in Fleet ftreet, London.

Where Gentlemen and Ladies may be supplied with fuch Instruments as are either Invented or Improved by himself; and Constructed according to the most perfect Theory.

H E Study of the Mathematicks being now become a neceffary Part of every Gentleman's Education, and as it contains an inexhaustible Fund of useful Knowledge, wherein the greatest Geniuses may exert their utmost Faculties, and the

the meanest find something within his Reach, the Theory of it displays an ample Field, and the Practice of it has always been productive of many great Advantages to Men of Action and Business.

As Mathematical Inftruments are the Means by which the Sciences of Geometry, Aftronomy, Philofophy, and Opticks, have been rendered ufeful in all the common and neceffary Occurrencies of human Life, they not only enable us to connect Theory with Practice, but alfo inftruct us how to turn bare Contemplation into the moft fubftantial Ufe, by making one of the moft ferviceable Branches of Learning the natural Way of rendering this Knowledge general and diffusive.
